## PREFACE.

The following work embraces the results of the whole of the long and laborious researches of the late Dr. Christian Heinrich Friedrich Peters on the Catalogue of Stars in Ptolemy's Almagest. Some account of this investigation, which he began about the year 1876, will be found in the opening pages. Quite unknown to each other, I had myself taken up the same subject in 1876 , but it was not until a few years later that some communications I made to the Royal Astronomical Society brought Dr. Peters into direct correspondence with me, and on learning that he was engaged in the same investigation of Ptolemy's Catalogue of Stars, I offered to place all of my materials at his disposal, and accordingly I sent him, for his free use, the collations of all the manuscripts I had made. These had been prepared with rather an undue amount of labor, as being closely engaged in manufacturing business far from London, it was only on rare days that I could visit the British Museum and other public libraries.

When Dr. Peters and myself met in Paris in April 1887, we had some long conversations on the subject. He told me he did not intend to visit England, and it was agreed that I should investigate all the sources of information possessed in the libraries there, and I particularly undertook to examine the Greek Selden Almagest at Oxford, and several Arabic manuscripts, and send him the results. In this and the following year many letters and discussions passed between us. In a letter dated August 14, 1888, received by Dr. Peters August 25, I asked what steps he had taken towards publication, and considering the contributions I had made from the manuscripts in this country, I asked "How far be would like, and would think it right, that my name should be associated with his as a joint author?" But I assured him "I was quite single-minded in the matter, and that my interest was removed from any idea of a personal character." This letter remained unanswered, probably because no steps had been taken towards preparing any part of the work for publication.

On July 18, 1890 , Dr. Peters died. It is unnecessary here to give an account of his life, which has been so fully dealt with in the addresses delivered on that occasion by Dr. Isaac H. Hall and Professor Oren Root, and in the pages of the monthly notices of the Royal Astronomical Society.

On September 3, I890, I addressed a letter to the executors of Dr. Peters, asking to be informed in what state his work on the Almagest remained with reference to publication, and requesting that the manuscripts might be sent to me to complete, and on November 9, 1891, all of his manuscripts and notes relating to this work, with some important exceptions, were sent to me.

The various subjects and sections of the investigation were each contained in a separate envelope. These were at once marked by letters and have been preserved in that state to the present day.

The following is the schedule:
Cahier A. Ulugh Beg. Collations and notes on various manuscripts by Peters and Knobel.
B. Aboul Hhassan. Notes and comparisons of his catalogues, all in pencil.
C. Collations of Greek, Latin, and Arabic manuscripts by Knobel.
D. Ptolemy's Catalogue of Stars. Final places with variants in 28 authorities, and comparison of the catalogue with modern observations.
E. Rough-draft catalogue of which revised copy is contained in D.
F. Reductions of the right ascension and declination of all stars to longitude and latitude.
G. Collations and notes of 24 manuscripts by Peters and 4 manuscripts by Knobel.
H. Translations of 6 chapters of the Almagest from Greek into German, minute German script in pencil.
I. Calculations and notes.on various catalogues, all in pencil.
J. Computation of proper motions; and comparison of the zodiacal stars in the Almagest with modern observations.
K. Comparison of Ptolemy's and other magnitudes with Harvard Photometry, all in pencil.

The examination of the manuscripts made it at once apparent that no preparation whatever had been made for publication. All the collations of manuscripts, notes, tables, and computations, were in very minute, close writing, and much of it in pencil, necessitating the copying out of most portions of the work for study, and in form for printer, involving much labor. Many notes were written in minute German script which have been troublesome and unduly expensive to translate. Among others are found several chapters from Books III, V, and VII of the Almagest, written in pencil in minute German script, being translations by Dr. Peters from the Greek into German, which have proved very difficult to decipher. No assistance towards the expense involved was obtainable in this country, and it seemed highly improbable that any society would undertake the publication of the work in the complete form which I considered indispensable. What to do under these circumstances has been a source of great anxiety.

On June 6, 1899, I met Professor Simon Newcomb in London, when he at once said he wished to see me about Dr. Peters' manuscripts. We adjourned to my club and discussed the matter fully for over half an hour. I explained my difficulties about publication and proposed that the work should be published in the United States. Professor Newcomb, referring to the Arabic and Greek, expressed a doubt whether they had the necessary type. No suggestion, however, was made for carrying out my proposal. I need only add that many years ago I made provision in my will that, on my death, the whole of the manuscripts and researches should be sent to the National Academy at Washington.

The present work is limited to the investigation of Ptolemy's Catalogue of Stars, but Dr. Peters also took up the question of Ulugh Beg's Catalogue, and for that purpose he collated several Persian manuscripts. I have added to this by collating all the Persian manuscripts of Ulugh Beg and the Arabic manuscripts of Al Sûfi to be found in this country. This it is hoped to publish in the future as a separate memoir.

It has been my object to make this investigation as exhaustive as possible, but where so much material has had to be examined, analyzed, and checked, and where the whole work has had to be done single-handed, it is hardly possible to
avoid some mistakes. The present investigation has shown how prone are all copyists to make mistakes; every care has been taken, and I can only hope that no very serious errors will be found.

I desire to record my obligations to the late Earl of Crawford, for kindly lending me the very valuable manuscript of the Almagest in his library; to the late Mr. Nicholson, Bodley's Librarian at Oxford, for the exceptional favor of sending the Bodleian Arabic Almagest to London for my examination; and to the late Dr. Rieu, Keeper of Oriental Manuscripts in the British Museum, for much valuable assistance.

I am much indebted to Prof. H. H. Turner for his kindness in supervising the reduction of the star places to the epoch B. С. Izo.

I desire to express my gratitude to the Hon. Elihu Root, to Professor E. C. Pickering, and to the Executive Committee of the Carnegie Institution of Washington, for their sympathy and interest in the work of the late Dr. Peters, and for the generosity which has now enabled his laborious and exhaustive researches on the most ancient Catalogue of Stars we possess, to be added to astronomical literature. E. B. Knobel.

32 Tavistock Square, London, W. C., October IgI4.

Fig. I.-Diagram (referred to on page 8) showing the errors in longitude and latitude of Ptolemy's Zodiacal Stars computed for the Epoch A. D. Ioo.

## HISTORICAL.

The Catalogue of Stars contained in the seventh and eighth books of Ptolemy's Mєүá $\lambda \eta$ इúva ${ }^{\prime} \iota s$, commonly called The Almagest, must always be considered of unique interest. It is the first and most ancient document we possess which gives a description of the heavens of sufficient exactness to admit of comparison with modern observations. For many centuries it was held in the highest repute, and indeed, until the time of Tycho Brahe it was practically the only source of information of the positions of the stars which the world possessed; for though in the fifteenth century Ulugh Beg prepared a much more accurate catalogue of Ptolemy's stars, it never came into general use. Ptolemy's catalogue has accordingly been the subject of many researches and investigations. Up to the present time six editions of the catalogue have been printed in Greek, viz.: Grynæus, Halley, Montignot, Halma, Baily, and Heiberg; also several editions in Latin, particularly those of Trapezuntius, Schreckenfuchs, and Flamsteed, translated from the Greek; those of Liechtenstein and Copernicus, translated from the Arabic by Gerard of Cremona, and the Alfonsine Tables, also translated from the Arabic. The translation into French from the Arabic of Abd Al Rahman AI Suffi, by Schjellerup, is simply Ptolemy's catalogue for a different epoch; and recently an edition of the Almagest has been published in German by Dr. Karl Manitius.

Dr. Peters began his study of Ptolemy's catalogue probably in 1876 or the early part of 1877 . In the latter year he wrote:*
> "A close examination of the exactitude of the catalogue of stars by Hipparchus, transmitted to us by Ptolemy, has never yet been made. Flamsteed, Lalande, and Bode have contented themselves with a merely superficial comparison of the separate positions of the stars. By happy conjectures Baily has corrected several of the figures which had been corrupted in the manuscripts; and for this same purpose a comparison will be found useful with the catalogue of Al Suffi, which is formed from the catalogue of Ptolemy by the addition of a constant to the longitudes. Nevertheless, many stars are left, the identification of which has not been possible or is doubtful. But if we wish to compare the condition of the starry sky at the time of the ancients with the present day, if we desire to recognize what has really changed in the sky during the last two thousand years, it is above all things necessary to know in how far a position of Ptolemy could be in all probability faulty." $\dagger$

> Dr. Peters was not content with the wealth of material offered by those editions of Ptolemy's catalogue which up to his time had been printed, and so, about the year 1883, he determined to investigate, as exhaustively as possible, all the various manuscripts containing the catalogue of stars which might exist in the libraries of Europe. In February 1884 he wrote: "During a journey made in Europe within the last few months, an opportunity was given me of examining in various libraries

[^0]the manuscripts of the Almagest which they contained." He began his investigations at Vienna, proceeding thence to Venice, Florence, and Rome. No further examination of manuscripts was made by him till the year 1887, when, taking advantage of a visit to Paris to attend the International Astrographic Congress, he then collated the important Greek manuscripts found in the Bibliothèque Nationale. The manuscripts he examined are given in the Table of Manuscripts Collated.

The investigation of Peters differs from all those hitherto made, for in order to assist in the identification of the stars, and to determine the actual errors of their positions, he began by calculating from modern observations the longitudes and latitudes of all of Ptolemy's stars, using for this purpose Piazzi's catalogue reduced to the epoch he assumed of A. D. Ioo, rather than to the epoch Ptolemy gives, which is the first year of Antoninus Pius, A. D. 138. These lengthy and laborious computations finally embraced every probable star near Ptolemy's places, corrected as far as possible for proper motion.

In his paper cited above, Peters compares 349 of Ptolemy's zodiacal stars, taken from the printed editions, with their computed positions for A. D. roo, and he arrives at the conclusion that the equinox requires a correction of $+34^{\prime} \cdot 9$, equal to a precession of 42 years. He also deduces that the errors in longitude as well as in latitude give evidence of considerable periodicity. He illustrates this with a diagram,* and says: "It will be seen that the curve of errors in longitude has its chief maximum close to $180^{\circ}$, and its chief minimum near to $0^{\circ}$ : the curve of errors in latitude has a maximum near to $140^{\circ}$, and a minimum near $320^{\circ}$." And he adds that "the conclusions arrived at from this as to the faulty erection of the instrument, and the position of the axes and circles of the armillary sphere which was used, will be seen more clearly when the comparison has been further extended to the stars outside the zodiac," but he did not pursue this interesting inquiry in that direction.

Dr. Peters brought into the whole investigation of Ptolemy's catalogue a rare ability, which it would be difficult to equal. Besides a fluent acquaintance with most European languages, he had an excellent knowledge of Greek, Latin, Hebrew, Arabic, Persian, and Turkish; and to these qualifications he added a high mathematical power and a facility and accuracy in computation which can only be fully appreciated by the examination of his papers. It is truly said that he was wonderfully swift in his perceptions, and this penetrating acumen is visible in the notes he made whilst collating and discussing the various authorities. Every manuscript was studied with scrupulous care, and every point of doubt investigated exhaustively. Nothing escaped his acute examination, and it is to be deplored that he was not spared to complete the publication of labors in which he had shown himself so preeminent.

Of the writer's share in the investigations contained in the present volume, it may be mentioned that in 1876 he first came to the determination of collating as many manuscripts as possible of Ptolemy's catalogue in order to obtain a more correct edition than we possessed. He commenced the work by the publication in

[^1]1876 of the Catalogue of Aboul Hhassan, which consists of 240 of Ptolemy's stars reduced to A. D. 622;* followed in 1879 by the collation of a Persian manu-, script of Ulugh Beg. $\dagger$ In 188I he collated three Latin manuscripts of the Almagest and the important Arabic Almagest in the British Museum, followed in 1885 by the collation of the Arabic Almagest contained in the Bodleian Library at Oxford, which Bodley's librarian had kindly sent to London for his investigation. Various other manuscripts were subsequently collated, and the whole of the material thus obtained was sent to Dr. Peters, and was discussed and used by him in the resulting catalogue. The manuscripts collated, together with some examined since Dr. Peters' death, are given in the Table of Manuscripts. One or two manuscripts of the Almagest are said to exist at the Escurial and at Toledo, but it has not been possible to examine them.

It may be safely asserted that no correct copy of Ptolemy's original catalogue exists in any manuscript, and where all codices contain so many errors it is difficult to say which copy is the most reliable. The centuries that elapsed between Ptolemy's period and the oldest manuscripts known have resulted in numerous errors in the longitudes and latitudes of the stars, due to the scribe, who was either careless or ignorant of what he was writing. Errors in the description of the stars would be very rare, as the scribe would understand the words, but in copying the letters signifying the figures of longitude and latitude he would have nothing whatever to guide him as to their correctness.

The original catalogue was doubtless written in the uncial Greek characters of the second century, for it is improbable that such a work would be written in cursive Greek. The form of the early uncial Greek letters suggests an explanation of some errors not so available from consideration of the Paris Codex 2389 and the Vatican Codex 1594, both of the ninth century. The majority of the errors found in the longitudes and latitudes of the stars must be ascribed to the early writing. All other Greek manuscripts are written in minuscule letters which first came into use only in the ninth century, and some errors may be due to this form of writing.

The most common error in all manuscripts is that of confounding the uncial Greek letters alpha $A=1$ and delta $\Delta=4$ (see Facsimiles). In the Table of the Collations of Manuscripts, examples of this error in all codices will be found in the longitudes of 44 stars and the latitudes of 36 stars. As such errors appear also in the Arabic codices, it would seem that they existed in the Greek used by Al Mamon for his translation about A. D. 827. Errors are found also from confusion between the alpha $A=1$ and the lambda $\Lambda=30$; such errors in Nos. 766 and 767 have been repeated by Grynæus and Halma, also errors of the lambda for the delta. On reference to the photograph of the Paris Codex 2389, the possibility of such confusion will be seen in the longitude and latitude of the twenty-second star of Ursa Major, which is not the case in the photograph of the Vatican Codex 1594. Another common error is mistaking the epsilon $\epsilon=5$ for theta $\boldsymbol{\theta}=9$, of which examples will be found in many manuscripts, in the longitudes of 12 stars, and the

[^2]$\dagger$ Mon. Nots. R. A. S., vol. XXXIX.
latitudes of 5 stars. In the Greek uncials of the second century these letters were circular in shape, with little difference between thick and fine strokes (see Facsimiles), and the opening in the epsilon for the cross-stroke was narrow; thus confusion between the two letters was very probable.

About the ninth century the kappa $K=20$ began to be written with the angular part of the letter removed from the vertical stroke. (See Facsimiles and the photograph of Venice Codex 313.) The effect of this was that the angular part was taken to be the character for $\ddot{\eta} \mu \tau \sigma=\frac{1}{2}$. Thus we find in most Greek manuscripts instances (Nos. 179, 277, 441, 572) where $K \Gamma^{\prime}$ has been taken to be $20^{\circ} \frac{1}{3}=20^{\circ} 20^{\prime}$, instead of $\mathrm{I}=10^{\circ} \quad<=\frac{1}{2} \mathrm{\Gamma}^{\prime}=\frac{1}{8}=10^{\circ} 50^{\prime}$. This is the explanation of the two readings of the latitude of No. 572 in the Paris Codex 2389.

Another error found in some manuscripts, particularly the Vatican Codex Reg. 90, and the Bodleian Codex 3374, where the minuscule $\nu=50$ is written for the $\eta=8$ or vice versa (which in form are quite dissimilar), is derived from the uncial letters, which sometimes closely resemble each other. This appears in the photograph of the Paris manuscript 2389, in the latitude of the eighteenth star of Ursa Major, where the uncial $\nu$ may easily be taken for the uncial $\eta=H$, but not so in Vat. I 594.

The above sources of difficulty in determining the probable original figures apply mainly to the degrees of longitude or latitude. As is well known, the minutes are always represented in Greek as fractions of a degree, where the significant letter with an accent expresses the denominator of the fraction. Innumerable errors occur from the omission of the accent, which then converts the letter into a whole number, affecting the degrees. Examples are given in the Facsimiles. The origin of the sign for ${ }_{\eta} \mu \mu \sigma v=\frac{1}{2}$ is rather obscure. As is seen in the Facsimiles, it takes various forms, becoming in later manuscripts and in printed Greek a form closely resembling the stigma 5 . One feature should be mentioned upon which Dr. Peters held a decided opinion, but which the writer finds it difficult to accept: The Greeks usually represented $40^{\prime}$ by $\Gamma_{0}$ or $\Gamma_{\beta}=\frac{2}{8}$, the $o$ in the first case being simply a contraction for $\beta$. They represented $50^{\prime}$ by the combination of $\frac{1}{8}+\frac{1}{3}$. But in several Greek manuscripts is found the combination of $\frac{1}{2}+\frac{1}{10}=40^{\prime}$ (see Facsimiles). Dr. Peters thought that this should be read as $\frac{1}{2}$, with variant $\frac{1}{10}$. But in no case is it written as all other variants yet noted, where the variant is always written above, or in the margin, or with some separation; and as this expression is found in so many manuscripts, it seems more probable that the characters should be read as a combination, and so they have been taken in the Table of Collations.

For nearly three centuries the only available edition of the Almagest in Greek was that published at Basel by Grynæus in 1538, but great uncertainty exists as to the manuscript he used. It is stated that the manuscript belonged to Regiomontanus, to whom it was given by Cardinal Bessarion, and that it was deposited at Nürnberg. No Greek manuscript of the Almagest exists at Nürnberg. Dr. Peters investigated the work of Doppelmayer (Histor. Nachricht. von der Nürenbergischen Mathematicis und Künstlern, Nürnberg, 1730), on which he made several notes. It appears that Regiomontanus devoted considerable study to the Almagest and to the other works of Ptolemy, and particularly to the commentary of Theon,
all of which he found in Rome in the original Greek. Bessarion presented to him the manuscript of Theon, which contained the following inscription in the Cardinal's writing: "Theonis in Ptolemæum liber meus Bessar. Cardin. Tuscul.," under which Regiomontanus wrote "nunc Johannis de Regiomonte." Doppelmayer states that Bessarion valued the Almagest so highly that he would not have exchanged it for a province, and he adds that this is attested by Camerarius in the dedication which he placed at che commencement of the Almagest printed at Basel in 1538 (Grynæus edition). On this point Doppelmayer is in error, for the dedication of Camerarius is to the commentary of Theon, and not to the Almagest. In the year 1450 one or two Greek codices of the Almagest had been found in Greece and brought to Rome. The first translation of them was made by Georgius Trapezuntius about 1460, subsequently published at Venice in 1528 ; this translation was not considered very correct, and Regiomontanus undertook a new translation, which, however, was never printed. When Regiomontanus died in Rome, July 6, 1476, Walther bought all his library and works and refused to allow any of the manuscripts to be printed or any inspection of the works. After the death of Walther, his library was dispersed, except a portion which was bought by a magistrate at Nürnberg.

The work given by Cardinal Bessarion to Regiomontanus was clearly the commentary of Theon, and there is no reliable evidence that Bessarion gave him a copy of the Almagest, which "he would be unwilling to exchange for a province." Doppelmayer states that Camerarius (real name Liebhard, born 1500 , died 1574) caused the Commentary of Theon to be added to the Almagest of Ptolemy in the edition published by Grynæus in 1538, "after the codex of Regiomontanus," presumably the codex of Theon.

The only further material evidence on the question is found in Montignot (Etat des Etoiles Fixes au second siècle par Claude Ptolemée, Nancy, 1780). He says: "The manuscript of the work of Ptolemy is an original document, carefully preserved in the library of Nürnberg. It was brought from Greece by Cardinal Bessarion, after the siege of Constantinople." (A. D. 1453.) "I ought to state that I had requested M. Moers to supply, from the manuscript of Nürnberg, some omissions of the catalogue, and to verify some longitudes which lead me to suspect mistakes of printing. I have followed very exactly the print of the Greek edition Basel 1538." Dr. Peters remarks: "As in the edition of Grynæus the latitudes of ${ }_{15}$, 16, and ${ }_{17}$ Ophiuchi are missing, and also the longitude and latitude of 21 Tauri, why did not Montignot supply them from the manuscript? The notes of Montignot about the manuscript said to be existing in Nürnberg must be regarded with distrust. Who was M. Moers? In the edition of Montignot there are absolutely no sure signs of a correction of the edition of Grynæus after an original manuscript." Delambre considered Montignot's edition "peu exacte."

The M. Moers referred to is no doubt Christophorus Theophilus de Murr, who in $\mathbf{1 7 8 6}$ published at Nürnberg a work entitled "Memorabilia Bibliothecarum pub. Norimbergensium." This work is not in the British Museum, but a copy exists in the Bodleian with manuscript notes by the author. It is quite clear that he mentions no manuscript of the Almagest at Nürnberg. The manuscript of Theon's
commentary on the Almagest, which he describes, has the following sentences: "Tô
 "Theonis in ptolemæum liber meus b. Card. Tusculani, nunc Ioannis de regiomonte. Donaverat nimirum Bessarion Regiomontano codicem." From the description by Zanetti (Græca D. Marci Bibliotheca) of the Venice Codex 310, which bears the autograph of Cardinal Bessarion, it has been considered that Grynæus based his edition on this manuscript. This is open to doubt, inasmuch as in this Venice Codex $\frac{2}{3}$ is always represented by gamma over beta, and never by gamma alone or beta alone, as in Grynæus. The oft-repeated statement that Grynæus based his edition on a manuscript given by Bessarion to Regiomontanus and deposited at Nürnberg is due to an erroneous reading of the above Greek sentence, which refers only to Theon's commentary.

In the Grynæus edition the whole number 3 is given by $\gamma$ or $\Gamma$. The use of the character $\Gamma^{\prime}$ is twofold. Throughout the work it represents $\frac{1}{3}=20^{\prime}$, but from the commencement to the end of Sagittarius (with the exception of the 15th star in Bootes) it also represents $\frac{2}{3}=40^{\prime}$. From Capricornus to the end, $\frac{2}{8}=40^{\prime}$ is represented by $\beta^{\prime}$. In the Paris Codex 2389, $\frac{2}{3}$ is represented by $\Gamma^{\prime} \beta$ or $\Gamma^{\prime} 0$, where $o$ is an abbreviation for $\beta$. This is in conformity with the manner of expressing fractions by the Greeks, viz., to write the denominator as an exponent. Thus, for example, in Archimedes, $\frac{9}{11}$ is expressed by $\theta^{t h}$, the numerator below the denominator. In our case $\frac{2}{8}$ is conformable to $\bar{\beta}^{\gamma \prime}$ or in uncials ${ }_{\beta} \Gamma^{\prime}$ or more simply $\Gamma_{\beta}^{\prime}$ finally $\Gamma_{\beta}^{\prime}$.

The Paris Codex Gracus 2394 exhibits many points of resemblance to the Grynæus edition. This manuscript is a copy, made in 1733 for the Bibliothèque du Roi, of a thirteenth century manuscript at Constantinople belonging to the Prince of Walachia, apparently afterwards destroyed by fire. The Paris manuscript has all the errors of print in Grynæus, but it has some omissions and it also gives some latitudes (248-250) which are wanting in Grynæus. It is significant that $\frac{2}{8}$ is represented in the first part of the catalogue by $\gamma^{\prime}$, and from Capricornus to the end by $\beta^{\prime}$, precisely as in Grynæus. This offers a strong probability that the manuscript used by Grynæus and the archetype of Paris 2394 had the same origin.

The Latin manuscripts are of less importance, though the translation from the Greek by Trapezuntius elucidates several doubtful points. It is uncertain which was the actual Greek manuscript used by Trapezuntius; it is stated to have been a copy of a Greek manuscript in the Vatican. The remaining Latin manuscripts are all copies of the translation from the Arabic by Gerard of Cremona, and may best be considered in connection with the Oriental codices. The principal error in all Latin manuscripts of the Middle Ages is confounding the figures 1 and 2, which sometimes are identical.

The Arabic manuscripts are especially valuable for comparison with the Greek, as the errors are of a different kind. Unlike the Greeks, who wrote the minutes of longitude and latitude in fractions of a degree, the Arabs wrote the minutes in figures, and thus these two different methods form a valuable check one on the other. In numerous cases where the Greek reading is vitiated by the omission of an accent, the correct value is found in the Arabic sources.

Two different and independent Arabic translations from the Greek are known: First, that of the British Museum Codex 7475. This is written in a very cursive character with a lamentable neglect of diacritical points, rendering it difficult to decipher. It is not written in the Maghribi or African character, but clearly it has been derived from a manuscript in that character. Secondly, that of the codices Bodleian 369, Laurentian 156, British Museum Reg. 16, and the manuscripts of Al Suffi, which are all from the same source, generally recognized as the translation from the Greek made by Al Mamon about A. D. 827. These manuscripts are written in the character called Neskhi, and in considering the probable errors of their texts it should be borne in mind that Neskhi, which is the ordinary form of Arabic writing, was only invented about the beginning of the fourth century of the Hejira=A. D. 9r2. Consequently the original translation of Al Mamon was probably in Cufic Arabic, and rewriting this into Neskhi would give an opening for very many errors. This adds a further difficulty to the problem of arriving at Ptolemy's original catalogue.

In the year 1887 Dr. Peters thus expressed to the writer his views on the value of the Arabic manuscripts:
"On the whole the Arabic sources agree all pretty well together in the figures of Ptolemy's catalogue. The Arabs were altogether much more accurate than the Greek scribes, so that I am able to reconstruct the version of Al Mamon's copy almost without doubt. We must try to reduce all that has come down to us of the catalogue of the Almagest to two sources: (1) the direct Greek tradition; and (2) the Arabic, which represents the copy of certainly high antiquity that Al Mamon brought home and had translated. We know that there were two translations of the Almagest made at Baghdad,* or that the first reduction was revised and improved upon several years later. This may account for some of the variants that are sustained, from both sides, by more than one of the sources of Arabic origin: I mean variants that do not come from the very frequent mistakes of the diacritical points."

The most common error in Arabic manuscripts is the omission of a diacritical point: thus the numbers 10 and 50 in combination differ only by a point; e. g., $\varepsilon=18$ and $\varepsilon=58$. Many such mistakes will be found in the manuscripts of Gerard of Cremona. Another common error is confusion between the Jeem $\tau=3$ and the Hà $\tau=8$, which seems to be due to the omission of a point, but in none of the manuscripts examined is the $\tau=3$ written in a form resembling the $\tau=8$, and it is more probable that the error may be traced to the Cufic original, where both letters are written exactly alike without any point. The letter Ya $=10$, when signifying ten, is most frequently written in the pure Cufic form. Confusion also occurs between the letters $T \bar{Z}=9$, and $\mathrm{Kaf} \underline{L}=20$, possibly due to the original Cufic letters here shown, which might easily be confounded. In the British Museum Codex 7475 there are several mistakes between 3 and 4, which in some writing might easily be made, and it is clear that the scribe was sometimes doubtful which was correct, as in those cases he has written both letters; and in the same manuscript there are several mistakes of 10,30 , and 50 in combination; the absence of the point making 10 and 50 alike, and writing the Lam $J=30$ rather short makes it indistinguishable from either. In all manuscripts there is frequently confusion between

[^3]the letters $\mathrm{Za} j=7$ written without a point, and Waw,$=6$. Examples of all these errors will be found in the Table of Collations, and it will be noted that such mistakes are quite different to those that occur in Greek.*

A curious series of mistakes, which appears to have escaped notice, is found in all manuscripts of Gerard of Cremona (A. D. 1114-1187), which were almost certainly made by him, and not by the copyist. The latitudes of 1 star in Ursa Minor, 5 in Draco, 8 in Cepheus, 9 in Hercules, 6 in Lyra, and 6 in Cygnus-that is to say, all stars of true latitude 60 and odd degrees-were all written as 300 and odd degrees. In some manuscripts a more recent scribe has altered these latitudes by erasure. It is not difficult to find an explanation. In all probability Gerard of Cremona learned his Arabic from the Moors. In the Maghribi or African numerical value of the letters, the letter $\operatorname{Sin} \cup^{\mu}=300$, but in the Neskhi or usual Arabic, that letter $=60$. The inference is that Gerard of Cremona used a manuscript from the East; that he was ignorant of the fact that the numerical value of the letters differed from that of the Moors or Western Arabs, $\dagger$ and had not sufficient knowledge of the subject to detect the gross mistake in the latitudes. $\ddagger$ The edition of the Almagest printed by Liechtenstein in 1515 is the translation of Gerard of Cremona in which these errors are corrected.

Baily's investigation of Ptolemy's catalogue (Memoirs Royal Astronomical Society, Vol. XIII) is limited to the printed editions of the Almagest, which he most carefully examined, and his notes on these editions and his identification of the stars are of great value and assistance. All references in the present work are to the ordinal numbers of his catalogue.

Ptolemy's Catalogue of Stars has been very fully discussed by Delambre, who has pointed out the error in the latitude adopted for Alexandria and the defects in the position of the armillary sphere employed, and he has also remarked on the neglect of the influence of refraction; so that it is only necessary to refer to the valuable appendix he contributed to Halma's translation. Colonel Drayson§ has discussed the method of observation adopted by Ptolemy, which he assumes as measuring the difference of longitude, first between the sun and the moon, and then that between the moon and the star. In the case of either of these bodies being near the horizon, he shows how it would be possible to introduce errors in the longitudes of the stars of as much as $\mathrm{I}^{\circ}$ due to the neglect of the influence of refraction.

One interesting feature was remarked by Dr. Peters, viz.: that the instrument used for the longitudes of the original catalogue was graduated differently to that used for the latitudes. With three exceptions, all in the constellation Virgo,

[^4]the minutes of longitude are either $10^{\prime}, 20^{\prime}, 30^{\prime}, 40^{\prime}$, or $50^{\prime}$; whereas in the latitudes there are 144 stars where the minutes are either $15^{\prime}$ or $45^{\prime}$, clearly indicating a difference in the graduation of the instruments.

It is not, however, at all clear from Ptolemy's description how his instruments were used, and it is needless to inquire very closely into that question, if the views of Delambre, Peters, and the writer are substantiated, that the catalogue is that of Hipparchus transmitted to us by Ptolemy. Dr. Peters made some calculations of the position of stars for B. C. 200, rather before the time of Hipparchus, but quite incomplete. In Catalogue III will be found the whole catalogue reduced to the epoch of Hipparchus B. C. 130, by deducting $2^{\circ} 40^{\prime}$ from Ptolemy's longitudes, being the difference which Ptolemy states he found between the longitudes of Hipparchus and those of his time, and leaving the latitudes unaltered. The catalogue thus reduced is compared with modern observations computed for the epoch of Hipparchus, and a subsidiary table (Table I) is added, showing the average errors in the longitudes for the two epochs A. D. ioo and B. C. 130. In the construction of this table stars of very uncertain identification and those with large errors in longitude or latitude are omitted. Notwithstanding Ptolemy's statement that he "observed as many stars as it was possible to perceive, even to the sixth magnitude," it will be seen that the above evidence confirms the theory that the catalogue is in all probability that of Hipparchus reduced by the addition of a constant to the longitudes, and retaining his original latitudes. The descriptions of the stars were probably amended by Ptolemy.

Reference has been made to Dr. Peters' early paper on the errors of Ptolemy's catalogue, and to the results which he derived from the printed editions of the Almagest. As many of the figures differ from the finally adopted catalogue now submitted, a new table of the mean errors of zodiacal stars has been made (Table II), and for comparison is appended the mean errors of the same stars for the epoch of Hipparchus B. C. i30 (Table III). It will be seen that all the inferences drawn by Dr. Peters in his original paper are not affected. The comparison of the longitudes of zodiacal stars only for A. D. roo shows a mean error of $+34^{\prime} .9$, equivalent to 42 years, making the true epoch of Ptolemy's Catalogue A. D. 58 , which is not very dissimilar to A. D. 63 adopted by Bode. The year A. D. 58 is 187 years after the epoch of Hipparchus, which gives a difference of precession of $2^{\circ} 36^{\prime}$, agreeing closely with the difference $2^{\circ} 40^{\prime}$ which Ptolemy states he found between the longitudes of Hipparchus and those of his time. It is clear that his correction to Hipparchus could not represent observed positions in A. D. 138, and the conclusion is obviously in support of the view that the catalogue is simply that of Hipparchus modified by a constant added to the longitudes.

Table I.-Comparison of the average errors of the longitudes in Ptolemy's Catalogue for the assumed epoch $A$. . Ioo, and the errors of Ptolemy's longitudes $-2^{\circ} 40^{\prime}$ for the epoch of Hipparchus B. С. 130 .

## NOTES ON THE MANUSCRIPTS OF THE ALMAGEST.

## GREEK.

1. Paris Codex 2389. This, and No. 19, Codex Vaticanus Græcus 1594, are the oldest manuscripts of the Almagest yet discovered. Codex 2389 was probably originally in the Laurentian library at Florence, and it was bought by Catherine de Medici, who brought it to Paris; on her death it probably came to the library, now the Bibliothèque Nationale. It bears the stamp in gold of Henri IV. The manuscript is assigned to Sæc. IX and is very clearly written in uncial Greek. Halma attributed it to the seventh or eighth centuries, but Dr. Peters was not inclined to this view. He remarks that it can not be older than the end of the ninth century, and says further:

> "Besides, it remains to be examined whether the writing is not, at least in parts, perhaps nothing but a copy of the older way of writing, and whether the handwriting itself is not of a considerably later date. To be noted is the transition of the sign for $\eta \mu / \sigma v$ into a later cursive (minuscule) form. A curious form of delta which occurs a few times was also taken into consideration."

The manuscript of the catalogue is in two forms of uncial Greek, and has apparently been written by two scribes. From the commencement to the end of the constellation Virgo, that is, to the end of Book VII of the Almagest, the writing is in the well-recognized characteristic form of uncial Greek of the ninth century. (Plate II.) The contrast of light and heavy strokes and a decline in regularity are characteristic. From the commencement of Book VIII, with the constellation Libra, to the second star in the constellation Hydra, the writing is in round uncials of a much older type. It is far more regular and is beautifully written. The letters $\boldsymbol{\epsilon}, \boldsymbol{\theta}, \mathbf{O}$, and $\mathbf{C}$, which in the first part are oval, are here circular. (Plate III.) It is probably from the consideration of this portion of the manuscript that Halma assigned it to the seventh or eighth centuries, as it certainly resembles writing of an earlier period. The peculiar form of delta noticed by Dr. Peters occurs only in this portion of the manuscript. It is apparently an ancient cursive form of the delta employed as far back as the second century. In the margin also are found a few examples of an old cursive form of the alpha. Dr. Peters remarks upon a variant to the longitude of the twentysixth star of Capricornus as if it was a small H which had been cancelled, but it is really an old cursive form of the letter $\eta$. The later form of the sign for $\eta_{\mu} \mu \sigma \nu$ referred to has not been detected, though this sign is written in several varying forms. From the third star in Hydra to the end, the writing is the same as the first part of the catalogue. M. Omont states that "the manuscript is homogeneous from beginning to end, and is written throughout by one scribe who varied his writing, inasmuch as the two forms of writing referred to are intermixed in various places, or possibly a second scribe was employed." The highest authorities assign the whole manuscript to the ninth century. Variants are in many cases added to the longitudes and latitudes of the stars, which indicate that the scribe copied from more than one manuscript or was doubtful of the exact character. For instance, in some cases where two readings are given of alpha and delta in the usual
letters, the scribe has written in the margin an old cursive alpha as explanatory.* The magnitudes are given very correctly. Writing 25 cm . high, 18 cm . wide.
2. Paris Codex 2390. About Sæc. XII. Clearly and neatly written in small characters with many abbreviations. Halma states that he used in his edition the Florence manuscript 2390. There is no manuscript of the Almagest at Florence so numbered. He thus describes it: "Il est au commencement du $\mathbf{1 2} 2^{\mathrm{me}}$ siècle; charactères très menus; très difficile à lire à cause du grand nombre de ligatures et d'abréviations de l'écriture." The mistakes he found, which are given by Baily, show an identity with Paris 2390, and there can be little doubt that its designation as a Florence manuscript is erroneous.
3. Paris Codex 239r. About Sæc. XV. Complete. Neatly written.
4. Paris Codex 2392. About Sæc. XV. Incomplete. The catalogue terminates with the third star of Corona Borealis. A very bad copy.
5. Paris Codex 2394. "Codex chartaceus Constantinopoli nuper in Bibliothecam Regiam illatus. Is codex descriptus est exemplari sæculo decimo tertio exarato, quod in illustrissima Valachix Principio Bibliotheca asservatur." The manuscript is a copy made in 1733 for the Bibliothèque du Roi. This copy shows that the resemblance of the archetype with Grynæus is very close. It contained all the errors of print of Grynæus, but having omissions, it can not be the manuscript used by Grynæus. It also had the latitudes of Baily's stars $248-250$, which are wanting in the edition of Grynæus.
6. Vienna Codex 14. About Sxc. XVI. Contains only the longitudes of the stars. It seems a copy of No. 14, the Laurentian Codex 39. The extreme errors seem to be the same as No. 20, the Vatican Codex Reg. 90.
7. Venice Codex 302. About Sæc. XV. In rather small minuscules, but the figures and accents are well and accurately written.
8. Venice Codex 303. About Sæc. XIV. Writing is distinct and some variants are written above the longitude and latitude. Some stars are omitted. The words $\mu \epsilon \dot{\jmath} \omega \nu$ and $\dot{\epsilon} \lambda \dot{\alpha} \sigma \sigma \omega \nu$ are omitted after Bootes and the magnitudes were not compared. It seems to be more correct than No. io. Venice Codex 3 II.
9. Venice Codex 3IO. About Sæc. XIV. Written in very clear and neat minuscules. The positions of the stars show much similarity to No. 12, Venice Codex 313, and particularly to No. r6, Laurentian Codex 48.
10. Venice Codex 3II. Given in Zanetti's catalogue as about Sæc. XII, but in Peters' opinion it is undoubtedly later. It is suggested by Morelli that this manuscript is a copy of Venice 313, or perhaps Venice 303. It is carelessly written, the $\mu \epsilon i \dot{j} \omega \nu$ and $\dot{\epsilon} \lambda a \sigma \sigma \omega \nu$ being repeatedly omitted, and there is some confusion.
II. Venice Codex 3r2. Zanetti gives the date about Sxc. XII; Morelli as about Sæc. XIII. The longitudes of the catalogue are those of Ptolemy increased by $17^{\circ}$. It is observable that the true longitudes of Ptolemy were first written and then the modified longitudes written over the first figures. Various errors in the zodiacal signs have resulted. In examining the volume Peters discovered some correspondence, dating from the year 1817, between Morelli and the Abbé Halma, from which it appears that Halma never had in his hands the Venice Codex, which he erroneously calls 313 instead of 312 . At his request Morelli sent him as a specimen a comparison of the positions of the stars in Ursa Minor and Ursa Major with Grynæus. A list of the positions where these differ is found in the original of one of Morelli's letters, and it is this list which Halma gives in his list of variants (vol. it, p. 435).

[^5]12. Venice Codex 313. Attributed by Zanetti to about Sæc. X, but considered by Morelli as Sæc. XI. This important manuscript is complete for the catalogue. Some few variants are given in the margin by the same hand. The magnitudes are given as correctly as in any other known manuscript. See further under No. 19, Vatican Codex 1594.
13. Laurentian Codex. Pluteus 28, I. About Sæc. XIII. Catalogue complete.
14. Laurentian Codex. Pluteus 28, 39. About Sæc. XI. Contains only Books VII and VIII. Catalogue gives descriptions and longitudes only, omitting the latitudes and magnitudes; the writing is large and clear. This seems to originate from the same source as Vienna Codex 14 and the Vatican Codex Reg. 90, the mistakes and omissions being the same, but the Vatican Codex contains the latitudes and is complete.
15. Laurentian Codex. Pluteus 28, 47. About Sæc. XIV. Badly written, and ink much faded. Seems to have been written by a learned man who paid more attention to the matter than to beauty of style.
16. Laurentian Codex. Pluteus 89, 48. About Sæc. XI. Beautifully written with great exactness, and with the additions of $\mu \epsilon i\} \omega \nu$ and $\hat{\epsilon} \lambda a ́ \sigma \sigma \omega \nu$ to the magnitudes. Much similarity between this manuscript and Codex Venetiis 3 Io.
17. Vatican Codex 1038. About Sæc. XII. The figures are clearly and plainly written, but sometimes without care. The copyist seems to have written vertically, so that the fractions are often displaced by one line. Halma (Preface, page lii) speaks of a manuscript at the Vatican numbered 560 , which contains the Almagest following a manuscript of Euclid. As the first portion of the Vatican Codex 1038 is occupied by a manuscript of Euclid, it is probable that this is the manuscript referred to as 560 .
18. Vatican Codex 1046. Sæc. XVI. Somewhat carelessly written. Contains the whole Almagest, but in the catalogue the figures for the positions and magnitudes are given only up to the thirteenth star of Draco. In a note the copyist complains of the contractions and illegibility of the archetype. Hence each book terminates with the remark $\Theta \epsilon \tilde{\omega}$ Xápıs (God be thanked). This may perhaps be the manuscript referred to by Halma as No. 184. (Preface, page lii.)
19. Vatican Codex 1594. Sæc. IX. The most beautifully written Greek manuscript of the Almagest thus far discovered.* (Plate IV.) This was investigated by Heiberg in his Greek edition of the Almagest, 1898-1903, and by Manitius in his German translation of the Almagest, 1912. The manuscript is written in small uncial characters with great regularity. Some variants are inserted in the margin. Notes in the margin are in very early form of minuscules. The whole of the catalogue appears to be written by one hand. The $\mu \epsilon i \bar{j} \omega \nu$ and $\bar{\epsilon} \lambda \dot{d} \sigma \sigma \omega \nu$ are correctly added to the magnitudes, and, with the exception of three stars in Cetus, agree with Codex Venetiis 313 . Several errors in the longitudes and latitudes are found equally in Venice Codex 313, indicating a common origin.
20. Vatican Codex, Reg.go. This codex is probably not very old, as the writer has used many contractions (vide Nos. 6 and I4).
21. Bodleian Codex, Selden 3374. Early Sæc. XIV. A perfect copy, beautifully written, without variants.

## LATIN.

22. Vienna Codex 24 (Trapezuntius). A fine codex written for Matthias Corvinus, but somewhat carelessly done, as the signs and notations of the latitudes are frequently omitted. The title is "Magnæ compositionis Claudii Ptolomæi libri a
[^6]Georgio Trapezuntio traducti." It is the translation from the Greek used for the Trapezuntius Almagest printed in 1528 . The codex does not seem to be a copy of No. 23 Codex Laurentianus 6. The date is given at the end, "Finis 17 Marcii, 467 ."
23. Laurentian Codex 6. Translation from the Greek by Georgius Trapezuntius. This Codex is dedicated to Pope Sixtus IV by Andreas Trapezuntius (son of the translator), which fixes the date between 1471 and 1484. It is carefully and clearly written.
24. Laurentian Codex 45. About Sæc. XIV. Beautifully written manuscript. Many variants added, some by the same hand, and others at a subsequent date. This, like the three following manuscripts, is a copy of the translation from the Arabic by Gerard of Cremona. There is a good deal of confusion in places and it does not appear to be a very accurate copy. As is found in other copies of Gerard of Cremona's translation, the $\mu \epsilon \dot{i} \zeta \omega \nu$ and $\epsilon \lambda \dot{\alpha} \sigma \sigma \omega \nu$ are indicated by the letters em and el .
25. British Museum Codex. Burney 275. Sæc. XIV. Translation from the Arabic by Gerard of Cremona. Formerly belonged to Pope Gregory XI (1370-1378) and was given by Clement VII to the Duc de Berri in 1387. It is a complete copy of the Almagest, beautifully written throughout, with handsome illuminations. The $\mu \epsilon i j \omega \nu$ and $\epsilon \lambda \dot{\alpha} \sigma \sigma \omega \nu$ are entirely omitted from the magnitudes.
26. British Museum Codex, Sloane 2795. Translation from the Arabic by Gerard of Cremona. The date of this manuscript is placed by Sir Edward Maunde Thompson as "circa 1300, possibly earlier, but hardly before the accession of Edward I, 1272." It is clearly written, but with many mistakes. The letters $e m$ and $e l$ for $\mu \epsilon i \zeta \omega \nu$ and $\epsilon \lambda a ́ \sigma \sigma \omega \nu$ are only in some cases appended to the magnitudes. The manuscript is imperfect, wanting several books.
27. Crawford Codex. A very fine illuminated manuscript of the complete Almagest, belonging to the Earl of Crawford. Sæc. XV. Translation from the Arabic by Gerard of Cremona. The original from which this manuscript was copied was evidently difficult to decipher, for the scribe has left blank spaces for many words, sometimes giving only the initial letters. There is no indication as to latitudes being north or south. The second page begins with the following sentence not found in the Liechtenstein Almagest: "Liber hic præcepto Maimonis regis Arabum qui regnavit in Baldach (Baghdad) ab Alhazen filio Josephi filio Maire, Arithmetici, et Sergio filio Elbe, cristiano, in anno XII et CC sectæ Saracenorum (A. D. 827) translatus est." Weidler describes a manuscript "Peirescianus" of Ptolemy which has this sentence at the end. It is to be noted in the Crawford manuscript that the word "stellam" in the original has been written "terram," which offers an explanation of Liechtenstein's curious description of the second star in Orion; "quæ appropinquat ad terram (? stellam) in humero Orionis."
28. New College, Oxford, No. 28r. A very imperfect copy of Gerard of Cremona's translation. It contains the catalogue of stars. Descriptions are given to the stars only in the first eight constellations. The manuscript is carelessly written and contains numerous mistakes.
29. All Souls College, Oxford, No. 95. Baily quotes a reference to this manuscript by Fabricius. It is clearly the translation of Gerard of Cremona, but the catalogue of stars in Books VII and VIII is omitted, and it is evident that this was intentional, as the text follows on from Book VII, cap. 9, to Book VIII, cap. 2, which is on the Milky Way.

ARABIC.
30. Codex Laurentianus 156. A carefully written manuscript in Neskhi or ordinary Arabic characters. Presumably a copy of the translation made by Al Mamon about A. D. 827.
31. British Museum 7475. An incomplete copy of the Almagest, wanting the first six books. Dated A. H. $615=$ A. D. 1218 . It is written in rather cursive Arabic, not in the Maghribi characters, but probably derived from an African manuscript; there is a lamentable absence of diacritical points, which makes the decipherment difficult. It is evidently a different translation from the Greek to No. 30 or No. 32. Whereas in these two manuscripts the $\mu \epsilon i \zeta \omega \nu$ and $\epsilon \lambda \dot{\alpha} \sigma \sigma \sigma \omega \nu$ are expressed by the initials of the Arabic words (Kabir) and كبـيـر (Saghir) signifying "great" and "small," in British Museum 7475, the initials of the Greek words $f(\mathrm{Mim})$ and $\int(\mathrm{La} \mathrm{m})$ are given. Many of the longitudes and latitudes differ from all other authorities.
32. Bodleian Arabic Almagest, Pocock 369. Dated A. H. $799=$ A. D. 1396. A wellwritten complete copy in Neskhi or ordinary Arabic. It compares with No. 30 in being presumably a copy of Al Mamon's translation.
33. British Museum Arabic Manuscript, Reg. 16, A. VIII. A compendium of the Almagest by Nassir Al Din Al Tusi, commonly called "Nassir Eddin." A very beautiful and accurately written codex in Neskhi characters. The most carefully written Arabic manuscript yet examined. Sæc. XV or XVI. On the first page is written, "This booke belonged to Sultan Ahmed ye Turkish Empr. and cost about 100 crownes at ye first." The catalogue is complete, and several resemblances with Bodleian Pocock 369 indicate that these two manuscripts had a common origin, though the copy of Nassir Eddin is more accurate. From the identity in the descriptions of the stars, the catalogue is taken from the translation of Al Mamon.

Table V.-Errors in manuscripts.
Stars.
Errors of $s=6^{\circ}$ and $s^{\prime}=10^{\prime}$. Longitudes. 3, 281, 305, 354, 439, 508, 685, 716, 777, 861, 1022.
Latitudes. I, 121, 233, 376, 436, 476, 501, 509, 513, 596, 686, 913, 980.
Errors of $\Gamma=3^{\circ}$ and $\Gamma^{\prime}=20^{\prime}$. Longitudes. 180, 207, 375, 448, 452, 478, 686, 849, 899, 992.
Latitudes. $4^{2}, 66,129,134,154,432,449,487,572,625,701,733$, $748,757,954,958,1000$, 1012.
Errors of $\Delta=4^{\circ}$ and $\Delta^{\prime}=15^{\prime}$. Longitudes. 533.
Latitudes. $\quad 83,86,103,138,141,395,399,402,471,645,752,769$.
Errors of $\boldsymbol{\epsilon}=5^{\circ}$ and $\boldsymbol{\Theta}=9^{\circ}$. Longitudes. 19, 75, 90, 329, 34I, 458, 524, 569, 570, 604, 605, 973 .
Latitudes. 28I, 558, $755,810,855$.
Errors of $A=1^{\circ}$ and $\Lambda=30^{\circ}$. Longitudes. 121.
Latitudes. 766, 767, 980, 983, 994.
Errors of $\Lambda=30^{\circ}$ for $\Delta=4^{\circ}$ Longitudes. IOI3, 1015 .
Errors of $\Delta=1^{\circ}$ and $\Delta=4^{\circ}$. Longitudes. 29, $155,157,158,234,265,376,382,383,402,415,463$, $464,465,485,486,488,495,534,539,542,544,623$,
$644,675,682,745,749,775,782,783,797,804,829$, 890, $912,915,970,971,983,999,1008,1020,1025$.
Latitudes. 52, $71,73,76$, $111,166,167,185,193,196,212,266$, 308, $335,357,369,429,497,534,606,662,698,715$, 729, 739, 758, 759, 760, 813, 879, 897, 955, 959, 969, 998, 1028.

## THE CATALOGUE.

The longitudes, latitudes, and identifications of the stars in the following catalogue are almost entirely those decided on by Dr. Peters from a full consideration of all the materials. In selecting from the different readings in the manuscripts, he took into consideration not only the agreement with the computed position, but also the fair accordance with the general errors in Ptolemy's longitudes of the particular constellation. From this it is inferred that the original observations of the stars were made by constellations, and not indiscriminately. As has already been mentioned, he computed from Piazzi the positions of all stars which might possibly be those observed by Ptolemy, reduced from A. D. 1800 to A. D. 100, which he assumed as the epoch of Ptolemy's longitudes.

The formula employed was

$$
l^{\prime}=l-23^{\circ} 30^{\prime} .1+13^{\prime} .6 \cos l \tan b-0^{\prime} .7 \sin l \tan b \quad b^{\prime}=b-13^{\prime} .6 \sin l-0^{\prime} .7 \cos l
$$

The computed positions are corrected as far as possible for proper motion from the following considerations:

For computing the influence of Proper Motions.
Generally

$$
d b=\cos \eta \cdot d \delta-\sin \eta \cdot \cos \delta d a \quad d l=\frac{\sin \eta}{\cos b} \cdot d \delta+\frac{\cos \eta}{\cos b} \cdot \cos \delta d a
$$

where

$$
\cos b \sin \eta=\sin \epsilon \cos a \quad \cos b \cos \eta=\cos \epsilon \cos \delta+\sin \epsilon \sin \delta \sin a
$$

or

$$
\begin{array}{rc}
\sin \eta=\frac{\cos a}{\cos b} \cdot \sin \epsilon & \cot \eta=\frac{\cos \delta}{\cos a} \cot \epsilon+\tan a \sin \delta \\
\cos \delta \sin \eta=\sin \epsilon \cos l & \cos \delta \cos \eta=\cos \epsilon \cos b-\sin \epsilon \sin b \sin l
\end{array}
$$

or

$$
\sin \eta=\frac{\cos l}{\cos \delta} \cdot \sin \epsilon \quad \cot \eta=\frac{\cos b}{\cos l} \cot \epsilon-\tan l \sin b
$$

Put

$$
S \sin \varphi=\cos \delta . d a \quad S \cos \varphi=d \delta \quad(S \text { and } \varphi \text { from Mädler's Bradley.) }
$$

$$
\Delta b=S \cos (\eta+\varphi) \quad \cos b \Delta l=S \sin (\eta+\varphi)
$$

or

$$
\Delta l=\frac{S \sin (\eta+\varphi)}{\cos b}
$$

For computing $\eta$, put
$\left.\begin{array}{l}m \sin M=\sin \epsilon \sin a \\ m \cos M=\cos \epsilon\end{array}\right\} \tan M=\sin a \tan \epsilon . \quad$ ( $\cos M$ always positive).
or

$$
\left.\begin{array}{l}
n \sin N=\sin \epsilon \sin l \\
n \cos N=\cos \epsilon
\end{array}\right\} \tan N=\sin l \tan \epsilon . \quad \text { (cos } N \text { always positive). }
$$

then

$$
\begin{array}{cc}
\cos b \sin \eta=\cos a \sin \epsilon & \cos \delta \sin \eta=\cos l \sin \epsilon \\
\cos b \cos \eta=\frac{\cos (M-\delta)}{\cos M} \cdot \cos \epsilon & \cos \delta \cos \eta=\frac{\cos (N+b)}{\cos N} \cdot \cos \epsilon
\end{array}
$$

If $S$ is given in seconds for I century (as in Mädler), $\Delta b$ and $\Delta l$ are desired in minutes for the time of $n$ centuries before the epoch; $S$ is to be multiplied by the factor $-\frac{n}{60}$. For example, if $n=20$ (which is about the time of Hipparchus), $S$ is to be multiplied by $-\frac{20}{60}=-\frac{1}{3}$.

Usually $\eta$ is between $0^{\circ}$ and $\pm 90^{\circ}$, and may be computed simply from

$$
\sin \eta=\frac{\cos l}{\cos \delta} \sin \epsilon
$$

But when $\cos (N+b)$, i.e., $\cos \eta$ negative, $\eta$ is between $\pm 90^{\circ}$ and $180^{\circ}$. Computing (roughly) $N$ from $\tan N=\sin l \tan \epsilon$, it is easily seen, when $N+b> \pm 90^{\circ}-$ which will be only for stars near the pole of the ecliptic.

The following table gives $N$ from $10^{\circ}$ to $10^{\circ}$ computed with $\tan \epsilon=9.6376$ (for 1800):
$\tan N=\sin l \tan \epsilon$

| $l$ | $N$ | $l$ | $N$ | $l$ | $N$ |

## PTOLEMY'S CATALOGUE OF STARS.

## CATALOGUE I.

The first column gives the number of the star in Baily's edition of Ptolemy's catalogue; the second gives Ptolemy's number and the description of the star in Latin, the text being taken from the Trapezuntius Almagest 1528, and revised from the Greek; the third gives the modern name; the fourth gives the longitude in signs, degrees, and minutes; the fifth the latitude; and the sixth the magnitude.

An asterisk $\left(^{*}\right)$ is appended to those longitudes and latitudes which differ from Baily.

## CATALOGUE II.

Ptolemy's Catalogue Compared with Modern Observations Reduced to Epoch A.D. ioo.
The first column gives the number of the star in Baily's edition; the second, Ptolemy's number; the third, Ptolemy's longitude in degrees and minutes with some alternative readings; the fourth, Ptolemy's latitude with some alternative readings; the fifth column gives Ptolemy's magnitude; the sixth column gives the modern name; the seventh and eighth columns give the longitude and latitude of the identified stars for the epoch A. D. Ioo, reduced from Piazzi's Catalogue, with the exception of the stars in Danckwortt's Catalogue (Vierteljahrsschrift der Astronomische Gesellschaft, 1881); and those in the catalogue of Neugebauer (Sterntafeln von 4000 vor Chr. bis zur Gegenwart nebst Hilfsmitteln zur berechnung von Sternpositionen zwischen 4000 vor Chr . und 3000 nach Chr., 1912) which have been reduced from those catalogues respectively. The ninth column gives the magnitudes in the Harvard Revised Photometry, the combined magnitude being given for double stars; and the tenth and eleventh columns give the differences of the computed positions of longitude and latitude.

## CATALOGUE III.

Ptolemy's Catalogue, showing the Longitudes reduced by $2^{\circ} 40^{\prime}$ and the Latitudes unaltered, compared with Computed Positions for the Epoch of Hipparchus, B. C. 130, derived from the same Modern Catalogues as used for Catalogue II.

## NOTES TO THE CATALOGUE OF STARS.

The following notes to the stars include all those found in Dr. Peters' manuscripts. These consisted of brief notes and remarks all written in pencil on various papers. Some of his earlier notes, communicated to Harvard Annals, Vol. XIV, are superseded by later researches.
3. Long. Most authorities have $16^{\circ} 0^{\prime}$, an error of $\mathrm{I} s=16^{\circ}$, for $1 s^{\prime}=10^{\circ} 10^{\prime}$.

Lat. Most Greek manuscripts have $74^{\circ} 20^{\prime}$, and the Arabs $74^{\circ} 0^{\prime}$-either $\mathbf{O} \Delta \Gamma^{\prime}$ or $\mathbf{O} \Delta$; it is more likely that the $\Gamma^{\prime}$ was omitted than that it was added.
6. Long. Paris 2389 , Vat. 1594 , and all the Arabs give $17^{\circ} 10^{\prime}$. Manitius has $17^{\circ} 30^{\prime}$.
12. Long. Baily gives $26^{\circ} 30^{\prime}$.
13. Long. Baily and most Greek and Arab manuscripts have $26^{\circ} 4^{\circ}$. Trapezuntius and Gerard of Cremona give $27^{\circ} 40^{\prime}$, which has been adopted. Confusion in Arabic between 6 and 7 is very common, but it is not easy to explain an error in Greek of $s=6$ for $Z=7$.
18. Lat. Baily and all Greek manuscripts give $44^{\circ} 0^{\prime}$. Sûfi, B. M. Reg. 16, and Bod. 369 have $45^{\circ} \mathrm{o}^{\prime}$. All are clearly erroneous. Sûfif finds no fault with the position. The star is certainly Fl. $30 \varphi$, which is described by Sûfi and was observed by Ulugh Beg. Peters conjectures that in the original uncial
 and thus resembled $M \Delta=44^{\circ} 0^{\prime}$.
25. Long. Baily gives $22^{\circ} 30^{\prime}$.
26. Long. Baily gives $3^{\circ} 30^{\prime}$.
37. Lat. All authorities agree. Latitude is $I^{\circ}$ too large; it should be $M \Gamma^{\prime}=40^{\circ} 20^{\prime}$, not $M A \Gamma^{\prime}=41^{\circ} 0^{\prime}$.
4I. Long. Baily gives $12^{\circ} 10^{\prime}$. No star exists corresponding with the position in the Almagest. It was not identified by Baily or Schjellerup. Manitius considers it to be Fl. 8 Leo Minor. Peters conjectured that there was confusion in the Greek between $I B s^{\prime}=12^{\circ} 10^{\prime}$ and $I \in s^{\prime}=15^{\circ} 10^{\prime}$, which he adopts, and so arrives at the same star observed by Ulugh Beg (see photograph of Venice Codex 313 , where $\epsilon$ in the abbreviation for Mei $i \omega \nu \nu$ might possibly be taken for $\beta$ ). Bod. 3374 has similar error of $\epsilon$ for $\beta$ in the latitude, noted by Bernard about 1684 . All the Arabs give latitude $22^{\circ} 45^{\prime}$, Vat. $1594,22^{\circ} 30^{\prime}$.

Fig. 3.-Venice Codex 313.
42. Lat. Most authorities give $23^{\circ} 0^{\prime}$, but Ven. 313, Vat. 1594 and the Arabs have $20^{\circ} 20^{\prime}$, which is right. Baily and Schjellerup could not identify. Manitius considers it to be Fl. io Leo minor. Peters finds that the star is VIII 245.
57. The large proper motion of $61 \sigma, R . A .+o^{\prime} .0973, D e c .-I^{\prime \prime} .766$, makes the identification of this star right.
58. Lat. Baily and all Greek manuscripts have $8 \mathrm{I}^{\circ}{ }^{\circ} 20^{\prime}$; all the Arabs $8 \mathbf{I}^{\circ}{ }_{40} 0^{\prime}$, which is adopted.
66. Lat. All Greek manuscripts have the incorrect latitude; the Arabs are right. $\Pi \Gamma^{\prime}=80^{\circ} 20^{\prime}$ for $\Pi \Gamma=83^{\circ} 0^{\prime}$.
69. Long. All the Greek manuscripts have the erroneous longitude of $10^{\circ}{ }^{2} 0^{\prime}$; the Arabs are right. $\quad \Gamma^{\prime}$ for $I \Gamma$.
75. Long. Baily adopts $5^{\circ} 10^{\prime}$ from Gerard of Cremona. All the Greek manuscripts have the erroneous longitude of $9^{\circ} 0^{\prime}$. The Arabs have $5^{\circ} \mathrm{O}$, which is correct. One of the numerous errors of $\boldsymbol{\theta}=9^{\circ} 0^{\prime}$ for $\boldsymbol{\epsilon}=5^{\circ} 0^{\prime}$.
79. Proper motion makes the disagreement in longitude much worse.
90. Long. Nearly all Greek manuscripts have the erroneous longitude $9^{\circ} 40^{\prime}$. The Arabs are correct with $5^{\circ} 40^{\prime}$. A similar error to No. 75.
96. This is the same star as No. 147.
97. Peters, Peirce, and Schjellerup identify this star as $\eta$ Coronæ, which accords with the description, but the position agrees better with $\chi$ Bootis, adopted by Bode, Halma, Delambre, and Manitius. Baily is undecided between $\eta$ and o Coronæ.

98. Not identified by Bode and Manitius. Baily and Schjellerup consider it to be $\chi$ Bootis, and Halma $\eta$ Coronæ. The description accords best with Fl. I o Coronæ.
99 to IO2. There is much diversity of opinion as to the identification of these stars. Peters considered that they were in the following order: $\omega, b, \psi$, and $c$; Schjellerup as $b, \omega, \psi$, and $c$; Bode, Baily, and Manitius, $c, \psi, b$, and $\omega$. The last accords best with the description and has been adopted. The comparisons for A. D. ioo are:

|  | Long. | Lat. |  | Long. | Lat. | $\Delta l$ | $\Delta b$ |  | Long. | Lat. | $\Delta l$ | $\Delta b$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{array}{r} \text { Ptolemy } 12 \\ 13 \\ 14 \\ 15 \end{array}$ |  | - 1 |  | $\bigcirc$, | $\bigcirc$, | ' | , |  | - ' | - , | , |  |
|  | 18810 | 4140 | $\omega$ | 18710 | 4021 | -60 | -79 | $c$ | 18833 | 4039 | +23 | $-61$ |
|  | 18640 | 4140 | $b$ | 18819 | 42 | +99 | +21 | $\psi$ | 18659 | 4230 | +19 | $+50$ |
|  | $187 \quad 0$ | 4230 | $\psi$ | 18659 | 4230 | - I | $\bigcirc$ | $b$ | 18819 | 42 I | +79 | -29 |
|  | 18740 | 4020 | $c$ | 18833 | 4039 | +55 | +19 | $\omega$ | 18710 | 4021 | -30 | 1 |

112. Lat. Baily and all Greek manuscripts have $46^{\circ} 30^{\prime}$; the Arabs have $46^{\circ}$ 10, which agrees best.
113. Baily has Long. $3^{\circ} 40^{\prime}$, Lat. $53^{\circ} 0^{\prime}$. He remarks that there is no authority for latitude $50^{\circ} 40^{\prime}$ adopted by Halma, but reference to the Table of Collations shows that nearly all Greek manuscripts have that latitude. Peters adopts $53^{\circ}$ Io' as in Sûfi and B. M. Reg. I6,
114. Lat. Baily gives $56^{\circ} 30^{\prime}$.
115. Lat. All the Greek manuscripts give $63^{\circ} 0^{\prime}$, which is wrong; the Arabs have the correct latitude, $60^{\circ} 20^{\prime}$. Error of $\equiv \Gamma$ for $\equiv \Gamma^{\prime}$.
116. Ptolemy's place is largely in error.

138, 139. Ptolemy's errors here are very large, and it is singular that the errors of the positions of these stars in Ulugh Beg are about as large. The identification of the stars is probably correct, but differs from Baily and Manitius.
140. Lat. Baily gives $72^{\circ} 15^{\prime}$. The latitude $72^{\circ} 0^{\prime}$ of the Arabs is adopted.
141. Lat. All the Greeks give $64^{\circ} 0^{\prime}$, and the Arabs $60^{\circ} 15^{\prime}$, which is correct. An error of $\equiv \Delta$ for $\Xi \Delta^{\prime}$.
146. Long. The longitude agrees closely with the computed position, but considering the large errors in Ptolemy's longitudes of the stars in Hercules, it is probably $I^{0}$ too large.
147. This is the same star as No. 96.
148. The identification of this star is probably correct, but the longitude and latitude are largely in error and no explanation of the discrepancy is available from the numerous manuscripts examined. Ulugh Beg has the correct latitude.
154. Long. There is no authority for the longitude $2^{\circ} 40^{\prime}$ assigned by Peters to this star. All the manuscripts give $I^{\circ} 40^{\prime}$. The very numerous errors in Greek of $A=1$ for $\Delta=4$ would suggest that here the longitude should be $4^{\circ} 40^{\prime}$, which agrees closely with the computed place; but seeing the large errors in longitude common to all the stars in Lyra, it is doubtful if this explanation is available.
I 56. Identified as Fl. $9 \nu^{2}$, which agrees a little better and also is brighter than $8 \nu^{1}$, which Baily has taken.
159. Lat. Baily gives the latitude $49^{\circ} 0^{\prime}$.
164. Long. Baily gives $19^{\circ} 20^{\prime}$.
175. Peters considers this star the combination of $43 \omega^{1}$ and $45 \omega^{2}$. All the Greek and Arabic manuscripts give the latitude as $63^{\circ} 45^{\prime}$, though $64^{\circ} 45^{\prime}$, adopted by Baily, agrees closer; Halley gives $64^{\circ} 50^{\prime}$.
184. Baily, Bode, Peirce, and Peters agree that this is $\iota$ Cassiopeia. Sûfiremarks that it is in a straight line with the two preceding stars $\delta$ and $\epsilon$, which proves the identification correct. The longitude is $4^{\circ}$ in error. All Greek and Arab authorities agree in Long. $\mathrm{I}^{\circ} 40^{\prime}$. The only explanation is an error in the earliest manuscripts of $A=1^{\circ}$ for $\Delta=4^{\circ}$, of which there are numerous instances in the manuscripts under discussion. Upon this explanation the difference of the computed place would be $+78^{\prime}$, harmonizing with the general errors of the longitudes in Cassiopeia. The latitude is $I^{\circ}$ in error, which is less easy to explain.
206. Lat. Baily and the Greek authorities give $28^{\circ} 0^{\prime}$, and the Arabs $28^{\circ} 15^{\prime}$, which is adopted.
 latitude as $\lambda a{ }^{\prime} \Gamma^{\prime}$. It is not clear what this means, but probably the iota has been written by mistake for the sign for $\eta \mu \mu \sigma v$; thus it would be $31^{\circ} 50^{\prime}$, as in Paris 2389 and Bod. 3374.
223. Lat. All authorities, except B. M. Arabic 7475, have latitude $20^{\circ} \mathrm{o}^{\prime}$; the latter has $22^{\circ} \mathrm{O}^{\prime}$, which is more nearly correct. Ulugh Beg has $21^{\circ} 30^{\prime}$.
230. This is the same star as No. 400.
231. Long. All authorities, except B. M. Arabic 7475, have $26^{\circ} 0^{\prime}$, which is $1^{\circ}$ too small. B. M. 7475 has $27^{\circ} 0^{\prime}$, which is correct. See note to No. 13.
233. Long. Baily gives longitude $20^{\circ} 40^{\prime}$, latitude $16^{\circ} 20^{\prime}$. Most of the Greek manuscripts have $20^{\circ} 40^{\prime}$, an error conjectured of $K \Gamma$ for $K \Gamma$. Paris Cod. 2394, $23^{\circ} \mathrm{O}^{\prime}$, which is adopted. Grynæus $20^{\circ} 20^{\prime}$, error of $\mathrm{K} \Gamma^{\prime}$ for $\mathrm{K} \mathrm{\Gamma}$. For
latitude there are the readings $16^{\circ} 20^{\prime}$ and $10^{\circ} 20^{\prime}$; the latter is adopted. Sûfi remarks upon the erroneous position of Ptolemy, and Ulugh Beg did not find the star. The nearest star to the position is Fl. 5, but this is only 6.7 mag . The largest star in the neighbourhood is Fl. 2 of 5.0 mag., identified by Manitius, but this gives the large errors of Long. $-56^{\prime}$ and Lat. - $150^{\prime}$.
235. Lat. All authorities have $27^{\circ}$, which is $I^{\circ}$ too small.
236. Lat. The Greek authorities have $26^{\circ} 30^{\prime}$ and the Arabs $26^{\circ} 45^{\prime}$.
239. There is great discordance in the manuscripts as to the coördinates of this star. The identification by Baily, Peirce, and Peters as Fl. io $\lambda$ is probably correct. The Arabs have the correct longitude. The latitudes, as appear in the table, are very discordant. Peters considered the latitude as $23^{\circ} 30^{\prime}$ or $23^{\circ} 50^{\prime}$. Cod. Ven. Greek 311, B. M. Reg. 16, and the Laurentian Arabic I 56 have $23^{\circ} 45^{\prime}$. Bodleian Arabic 369 has $28^{\circ} 45^{\prime}$, which by the common error in Arabic of $\tau=8$ for $\mathbb{C}=3$ may well accord. Probably $23^{\circ} 45^{\prime}$ is the best to adopt. Baily has latitude $33^{\circ} 50^{\prime}$.
246. Long. Baily and the Greek manuscripts give $26^{\circ} 40^{\prime}$, which is erroneous; the Arabs and one reading of Paris 2389 have $23^{\circ} 40^{\prime}$, which is correct. Peters remarks that if the Greek longitude is right, the star might be the Nova 1604, but Ulugh Beg observed the star $40 \xi$. This identification is confirmed by Peters, Baily, and Manitius.
247 to 250 . Peirce states that these stars present one of the greatest perplexities of the whole catalogue. On reference to the Table of Collations, it will be seen that the manuscript authorities are about equally divided as to the latitude being north or south. Paris Codex 2389 gives both, which indicates that it is a compilation from more than one manuscript. Grynæus gives 247 as north, and omits any designation to $24^{8-250}$, and it is singular that these are the only omissions in his whole catalogue of designation of the latitude, probably from the conflicting evidence in the manuscripts he used. The only printed editions which give the latitude of all these stars as south are Copernicus and Clavius. Peirce has discussed these stars in H. A. Vol. IX, but he is in error in stating that Baily has altered the latitude of the 16th star, No. 249. Peters' investigation leaves little room for doubt of his correct identification of the stars, and of their latitudes being south. The longitude of 250 is largely in error.
250. Lat. Baily has $0^{\circ} 45^{\prime}$, which is found only in Liechtenstein and B. M. 7475 .
251. There is some uncertainty as to the identification of this star. All manuscripts agree in longitude and latitude. Schjellerup and Manitius identify as Fl. 58, which would make the longitude erroneous by $2^{\circ}$ and the latitude $\mathrm{I}^{\circ}$. Bode and Halma give Fl. $2 e$ (Sagittarius). The nearest star to the position is Fl. 52 (adopted by Baily), which is 6.6 mag. It has been conjectured that the star may have been Nova 1604, the position of which for A. D. 100 is longitude $236^{\circ} 44^{\prime}$, latitude $+2^{\circ} 2^{\prime}$, a difference of $\mathrm{I}^{\circ}$ in each coördinate. Peters does not decide between 52 Ophiuchi and 2 Sagittarii.
255. The Arabs have the correct latitude $\mathrm{I}^{\circ}{ }_{40^{\prime}}$; Baily has $\mathrm{I}^{\circ} 5^{\prime}$.
262. Sûfi calls this a double star, which is Fl. 7 I and 72 together.
268. Long. Most authorities and Baily give $23^{\circ} 10^{\prime}$, which is $I^{\circ}$ too small. Paris 2389 gives $26^{\circ} \mathrm{I} 0^{\prime}$, which is nearer the computed place but is discordant with the other longitudes as being too large.
274. Lat. All authorities, Greek and Arabic, have latitude $16^{\circ} 15^{\prime}$. But there is no suitable star in latitude $16^{\circ}$. Baily states that Bode and Delambre give it as $13^{\circ} 15^{\prime}$, but without authority. Bode, however, gives it as $13^{\circ} 0^{\prime}$.

There is no doubt that $13^{\circ} \mathrm{I} 5^{\prime}$ is taken from Halley's edition of the Catalogue (Geographia Veteris Scriptores Graci Minores, r7I2) which is a copy in which the positions of the stars have been corrected by computation.* It is probable that the identification of the star as Fl. $3 v$ Ophiuchi is correct, and Ulugh Beg certainly observed this star. The latitude should be $13^{\circ} 15^{\prime}$, and so it has been adopted by Peters. No explanation of the error in Greek is available.
285. Lat. Baily has $37^{\circ} 40^{\prime}$, but the Arabs have $38^{\circ} 40^{\prime}$, which is adopted.
289. Bode, Halma, Delambre, Baily, and Manitius make this star Fl. 54 o. Peters remarks that Fl. $59 \xi$ is Ulugh Beg's star and probably that of Ptolemy, but the latitude is $\mathrm{I}^{\circ}$ too large; besides $\xi$ is i magnitude brighter than $o$.
296. Long. Bod. 3374 and Ven. 302 have $50^{\circ} 50^{\prime}$, error of $\nu$ for $\eta$.
299. Longitude is $2^{\circ}$ too large and latitude $I^{\circ}$ too large.
300. Long. All authorities give $2 \mathrm{I}^{\circ} 10^{\prime}$, which is $\mathrm{I}^{\circ}$ too large. The position of this and the preceding star in Ulugh Beg are quite erroneous. Peters has adopted $20^{\circ} 10^{\prime}$.
304 and 309. Long. In these stars longitude is $\mathrm{I}^{\circ}$ too small.
305. Lat. Adopted from Grynæus and Paris 2394. Most authorities give $33^{\circ} 50^{\prime}$, which Baily adopts.
308. Lat. Several Greek and Arab authorities have $34^{\circ} 0^{\prime}$. Error of $\wedge \Delta$ for $\wedge \Delta^{\prime}$.
329. Long. Baily gives $9^{\circ} 1^{\prime}$.
332. Long. Comparison with Ulugh Beg seems to indicate an error of $\mathrm{r}^{\circ}$ too large in Ptolemy's longitude.
346. Lat. Vat. 1594, Ven. 310 and 313, and all the Arabs have the correct latitude.
356. Lat. All authorities have $32^{\circ} 30^{\prime}$, which is $1^{\circ}$ too large, which is confirmed by comparison with Ulugh Beg.
357. Peters confirms Peirce in identifying this star as Fl. I o.
360. Long. There appears to be no authority for $16^{\circ} 40^{\prime}$ adopted by Baily.
368. Latitude appears to be $I^{\circ}$ too large; Ulugh Beg has $3^{\circ} 12^{\prime}$; all authorities give $4^{\circ} 30^{\prime}$ or $4^{\circ} 50^{\prime}$.
37I. The position of $63 \tau^{2}$ Arietis agrees much better than $61 \tau^{1}$, and was certainly the star observed by Ulugh Beg.
372. Lat. Baily has $1^{\circ} 30^{\prime}$.
374. The position agrees well with Fl. $87 \mu$ Ceti (see note to 716 and 717 , Ptolemy's 5 and 6 Ceti). Schjellerup, following Bode, identifies both 374 and 717 as $\mu$ Ceti. The agreement of Ulugh Beg with Ptolemy is so good that there can be no doubt that they observed here $\mu$ Ceti, while 717 does not agree at all. Manitius identifies 374 as Fl. 38, but the position for A. D. 100 is discordant. $\Delta$ long. $=+70^{\prime} ; \Delta$ lat. $=+107^{\prime}$.
375. Lat. Baily has $10^{\circ} 30^{\prime}$.
382. Long. Baily has $24^{\circ} 20^{\prime}$, but the Arabs have probably the more correct longitude, $24^{\circ} 4^{\prime}$.
383. Long. All Greek manuscripts, except Ven. 311 , have erroneously $21^{\circ} 20^{\prime}$. An error of $K A=2 I^{\circ}$ for $K \Delta=24^{\circ}$.
389. Both longitude and latitude about $\mathrm{I}^{\circ}$ too large. Vat. Reg. 90 and Manitius give longitude as $10^{\circ} 20^{\prime}$, an error of $1 \Gamma^{\prime}=10^{\circ} 20^{\prime}$ for $I \Gamma=13^{\circ}$.
392. Ptolemy probably observed $\theta^{1}$ and $\theta^{2}$ as one mass.
394. Longitude $1 I^{\circ} 50^{\prime}$ is adopted from all the Arabs, one reading of Paris 2389 and Ven. 312. Baily has $12^{\circ} 50^{\prime}$, also from a variant in Paris 2389.

[^7]395. Long. The Arabs give $17^{\circ} 10^{\prime}$ and the Greeks $17^{\circ} 30^{\prime}$, as adopted by Baily; the first is preferable. Latitude in Paris 2389 is erroneously $0^{\circ} 15^{\prime}$; error of $\Delta^{\prime}=0^{\circ} 15^{\prime}$ for $\Delta=4^{\circ} 0^{\prime}$.
399. Lat. All authorities have $4^{\circ} 0^{\prime}$, which is wrong; error of $\Delta=4^{\circ} 0^{\prime}$ for $\Delta^{\prime}=0^{\circ} 15^{\prime}$. B. M. 7475 makes the latitude north, all the others south. Latitude $+0^{\circ} 15^{\prime}$ would give the best accordance.
400. This is the same star as No. 230.
402. Lat. The Arabic Bod. 369 and B. M. Reg. 16 are the only authorities which have the correct latitude $0^{\circ} 15^{\prime}$; all others, including Sûfi, have $4^{\circ} 0^{\prime}$. Sûfi remarks that "Ptolemy's latitude is false, as the latitude places the star north of the preceding star, whereas the description states that it is south." This shows that the manuscript of Ptolemy used by Sûfi had the same error as in No. 399 above, viz., $\Delta=4^{\circ} \mathrm{o}^{\prime}$ for $\Delta^{\prime}=0^{\circ} 15^{\prime}$.
404. Paris 2390, and the two Venice codices, 310 and 313 , give the latitude correctly south.
405. Long. All manuscripts agree in giving $8^{\circ} 0^{\prime}$; Manitius has $8^{\circ} 30^{\prime}$.
406. The identification of this star is not free from doubt. Baily and Halma considered it to be $42 \psi$ Tauri and this star was finally adopted by Peters, but he remarks that Ulugh Beg's position of Ptolemy's 27 th star in Taurus agrees fairly with 41 Tauri, but badly with $42 \psi$. Ptolemy's star is in better harmony with 4r Tauri if we could assume an error of $I^{\circ}$ in the latitude. The errors for A. D. 100 are:

|  | $\Delta$ Long. | $\Delta$ Lat. | Mag. |
| :---: | :---: | :---: | :---: |
| 41 Tauri. | + 2 | $-57$ | $5 \cdot 3$ |
| $42 \psi$. | +25 | +32 | $5 \cdot 3$ |

Baily adopts latitude $7^{\circ} 20^{\prime}$.
410. Long. Baily has $2^{\circ} 20^{\prime}$.
412. Peters considered that there was no doubt that this star is III 170 and not Fl. 18 as Baily has, which gives errors for A. D. 100 of Long. $-27^{\prime}$, Lat. $-19^{\prime}$, mag. 5.6. III 170 gives errors of Long. $+51^{\prime}$, Lat. +9', mag. 5.4. The star can not be Alcyone. Ptolemy describes it distinctly as $\mu$ ккрòs (small). Gerard of Cremona gives mag. 5; all other authorities mag. 4.
415. The longitude $24^{\circ} 0^{\prime}$ is adopted from one reading in Paris 2389, Venice 303, 311 , 312, and the Arabs. The difference with other manuscripts is the common confusion of the alpha and delta. Baily has $2 \mathrm{I}^{\circ} \mathrm{O}^{\prime}$.
418. Peters, Peirce, and Manitius identify as Fl. 129 observed by Ulugh Beg, but the star is rather small and the longitude is too small. Peirce suggests that it might be better to make 418 as Fl. 126, and to suppose that 417 had disappeared. The position of Fl. 126 for A. D. 100 would accord very well with Ptolemy's star No. 418, but the identifications adopted accord best with the description.
419 to 423. Sûfi remarks that the longitudes and latitudes of these stars are grossly in error. There seems little doubt that Peters' identification is correct. Ulugh Beg's positions agree fairly well with them. They are all small stars.
424. Lat. Baily and all the Greeks have $9^{\circ} 30^{\prime}$, and the Arabs $9^{\circ} 40^{\prime}$, which is more correct.
426. Long. All authorities agree, but the longitude is $2^{\circ}$ too large. The latitude is too small. Bod. Arabic 369 gives $11^{\circ} 0^{\prime}$, which is more nearly correct.
432. Baily adopts longitude $26^{\circ} 10^{\prime}$, latitude $3^{\circ} 0^{\prime}$. The Greek manuscripts give longitude $26^{\circ} 10^{\prime}$, and the Arabs $23^{\circ} 10^{\prime}$; the latter is certainly the better to
adopt. The latitudes are either $\Gamma=3^{\circ} \mathrm{o}^{\prime}$ or $\Gamma^{\prime}=0^{\circ} 20^{\prime}$. Adopting the latter, the position agrees with Fl. 58. Baily identifies as 76 c. Peirce as 52 Tauri, Schjellerup as $b$, and Manitius as 63 .
434. Lat. Baily adopts $18^{\circ} 15^{\prime}$ from all authorities. Peters gives the longitude as $18^{\circ} \mathrm{I} 0^{\prime}$ for the reasons given on page 12 for believing that the instrument used for measuring longitudes was not graduated to $15^{\prime}$.
436. Long. Baily has $21^{\circ} 20^{\prime}$. There is great uncertainty in the latitude of this star in all Greek manuscripts and in the printed Greek of Grynæus and Halma. In all cases it is represented by the character for $\frac{1}{2}$ followed by that for $\frac{1}{6}$, or in Paris 2389 and Laurentian 1, by 6. There is a slight indication in Paris 2389 (though not in Laurentian I) of a separation of 6 from $\frac{1}{2}$, in which case it may be possibly $\frac{1}{2}$ with $6^{\circ}$ as a variant. Peters considered the majority of cases he examined to be $0^{\circ} 30^{\prime}$ with variant $0^{\circ} 10^{\prime}$, not $0^{\circ} 40^{\prime}$. All the Arabs agree in latitude $6^{\circ} 0^{\prime}$, which is adopted.
438. Long. The better reading is that given by the Arabs and Vienna 14.

445 and 446. Baily, who took the Greek descriptions of the stars from Grynæus, did not perceive the error in the descriptions of these two stars, which are equally erroneous in Paris 2389. He gives:
 $\gamma$. $(\tau \rho \stackrel{\omega}{\omega} \nu)$.
446. $\dot{\epsilon} \pi^{\prime} \epsilon^{\prime} \theta^{\prime} \dot{\epsilon}$ as $\dot{o} \beta \dot{b} \rho \in \epsilon \cos$. It is obvious that these descriptions should be as in Vatican 1594 thus:
 ßópetos.
446. $\dot{o} \mu \dot{\epsilon} \sigma o s \tau \bar{\omega} \nu \tau \rho \imath \tilde{\omega} \nu$. Baily also states that the latitude of 445 in Paris 2389 is $-2^{\circ} 40^{\prime}$, but in that manuscript it is clearly $-1^{\circ} 20^{\prime}$.
445 to 448. The longitudes of these stars are all in error. The authorities give longitude of 448 as $0^{\circ} 40^{\prime}$, except Laurentian 39, Vienna 14, and Vatican Reg. 90 , which give $3^{\circ} \mathrm{o}^{\prime}$, and Gerard of Cremona, B. M. Sloane 2795, which gives $5^{\circ} 40^{\prime}$, the same as Liechtenstein; the last has been adopted. Peters remarks, "There is no other star than $\zeta$ Cancri that suits the position," hence the longitude is $\mathrm{r}^{\circ}$ too large.
449. Lat. Baily has $0^{\circ} 20^{\prime}$. The value $0^{\circ} 40^{\prime}$ given by the Arabs has been adopted as agreeing better with the computed position, and also by comparison with Ulugh Beg.
455. Ptolemy's position is erroneous. Ulugh Beg is right.
457. Lat. Baily and all authorities give $7^{\circ} 30^{\prime}$. The error in latitude is remarked on by Sûfi and must be very old. Peters has adopted $10^{\circ} 30^{\prime}$ without authority.
458. Long. All authorities have $19^{\circ} 10^{\prime}$ (adopted by Baily) or $19^{\circ} 4^{\prime}$, except Bodleian Arabic 369 , and B. M. Reg. 16, which have $15^{\circ} 10^{\prime}$. Sûfi remarked the error in longitude. There is little doubt the Arabs are correct, and we have another instance of error in the Greek of $\boldsymbol{\theta}=9$ for $\boldsymbol{\epsilon}=5$. Peters identifies the star as the combination of $62 o^{1}$ and $63 o^{2}$. Sûfi and Ulugh Beg both observed o Cancri. Baily, Schjellerup, and Manitius consider the star to be $\pi$ Cancri.
459. Sûfi speaks of the error in longitude, which is $2^{\circ}$ too large.

460 and 46 r . The latitudes of these two stars are wrongly transposed in all the authorities.
472. Long. All authorities agree, still the longitude is $\mathrm{I}^{\dagger}$ too large. Ulugh Beg also has the longitude too large.
479. Long. Baily gives $12^{\circ} 10^{\prime}$.
482. The identification of this star is one of the most difficult in the catalogue. Ptolemy states that it is the northern of two stars, the southern, No. 483, being well identified as $\theta$ Leonis. Fl. 8I is possibly the star, in which case Ptolemy's
latitude would agree, but the longitude would be $4^{\circ}$ in error. Peters remarks, "if we will not assume that a star disappeared near X 251, mag. 6.8, then the correction of longitude $1 H \Gamma^{\prime}=18^{\circ} 20^{\prime}$ for $I \Delta \Gamma^{\prime}=14^{\circ}$ $20^{\prime}$ is the most plausible conjecture that can be made." There is, however, no evidence in the uncial Greek of papyri or of vellum manuscripts, nor in cursive Greek, of a confusion between $\mathrm{H}=8$ and $\Delta=4$. "Sûfi speaks of the error in latitude of Ptolemy, but this can not be Ptolemy's star, and Sûfi had another star in view, while Ulugh Beg in his observations was guided by Sûfi." "Baily's identification with 71 Leonis is entirely to be rejected, since Baily himself has shown that the R. A. of 71 Leonis in Flamsteed by mistake is $2^{\circ}$ too small."
486. Long. The authorities have either $24^{\circ} 40^{\prime}$ or $21^{\circ} 40^{\prime}$. The former is adopted, the latter is an error of $A=1$ for $\Delta=4$. The star is identified as $84 \tau$. Ulugh Beg observed $69 p^{5}$. Sûfi's description points to $74 \varphi$.
487. Lat. All the Greek manuscripts, with the exception of Vat. Reg. go, give the latitude as $3^{\circ} 12^{\prime}$, which is clearly erroneous. There is no other instance in the whole catalogue of the fraction $\frac{1}{5}$. The error is doubtless of very ancient date. The magnitude of the star is $\epsilon^{\prime}=5$, and the latitude and magnitude are written thus: $\Gamma \epsilon^{\prime} \epsilon^{\prime}$. It is probable that in an early manuscript the magnitude was written by mistake within the latitude column, whence the mistake arose. Manitius has latitude $3^{\circ}$ ro' as Vat. Reg. go. The Arabs have either $3^{\circ} 0^{\prime}$ or $0^{\circ} 20^{\prime}$, a confusion of $\Gamma^{\prime}$ and $\Gamma^{\prime}$. Latitude $3^{\circ} \mathrm{o}^{\prime}$ is correct and so no doubt it was given in the original Greek.
494 to 496. The identification of these stars seems correct, and these were the stars observed by Ulugh Beg. The large error they have in common makes it look as if they were determined either differentially or by some other observer. Thus may be explained also why they are called á auvós, while not smaller than many others.

|  | $\mathrm{C}-\mathrm{Pt}$. |  |
| :---: | :---: | :---: |
|  | $\Delta l$ | $\Delta b$ |
|  | - |  |
| 494. | +229 | - 135 |
| 495. | +2 45 | -1 34 |
| 496. | +325 | - 124 |

The following are the several identifications of the stars:

|  | Peters. | Baily. | Bode. | Halma. | Schjellerup. Manitius. |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| 494. | $15 c$ | $\ldots \ldots \ldots \ldots$ | $c$ | $e$ | $15 c$ | $15 c$ |
| 495. | $7 h$ | 4 Comœ. | $h$ | $h$ | 12 | 7 |
| 496. | $23 k$ | 21 Comœ. | $g$ | $g$ | 21 | 23 |

494 is given of magnitude 5, and is described by Ptolemy as $\lambda a \mu \pi \rho o ̀ s . ~ I n ~$ Paris 2389 and Vat. 1594 it is $\lambda a \mu \pi \rho o ̀ s ~ a \mu a v \rho o ̀ s ; ~ i n ~ t h e ~ T r a p e z u n t i u s ~ e d i-~$ tion "splendida," and in Liechtenstein, "luminosa." Ptolemy designates as $\lambda a \mu \pi \rho \dot{o}^{\prime}$, six stars mag. 1, thirteen mag. 2, seven mag. 3, and eleven mag. 4. He does not apply the word to any other star so faint as 494. It seems probable that here is a variable star.*

[^8]497, 498. The longitudes of these stars are interchanged in all the manuscripts. Baily has not corrected them. The longitude $25^{\circ} 20^{\prime}$ he gives to 497 should be that of 498 . All the Greeks have $25^{\circ} 20^{\prime}$, and the Arabs $26^{\circ} 20^{\prime}$, which is adopted.
504. Peters remarks that the stars Fl. 44, 46, and 48, Virginis, mags. 5.9, 6.1, and 6.5, are near together, which may explain the greater brightness, mag. 5, estimated by both Ptolemy and Sûfi. Combined mag. 5.o.
509. Lat. Greek authorities give $20^{\circ} 10^{\prime}$, the Arabs $15^{\circ} 10^{\prime}$. Ulugh Beg's latitude is $16^{\circ} 15^{\prime}$. Peters has adopted $16^{\circ} 0^{\prime}$ from Halma, who is copied by Baily, and he remarks that Halma gives no authority. It is clear that Halma took $16^{\circ} 0^{\prime}$ from Halley. It is of course correct, but is not supported by any manuscript.
513. Long. This is $\mathrm{I}^{\circ}$ too small; all authorities agree.
515. Peters and Baily agree that Ptolemy's position indicates $68 i$, and both remark that it is clear that this position can not form the south following corner of the quadrilateral Ptolemy speaks of. But it is evident that the position of Ptolemy's 20th star in Virgo (correctly identified as 86) is exactly in the south following corner of the quadrilateral formed by 74,76 , and 82 . The descriptions of Nos. 515 and 516 should be therefore interchanged.
517. Ptolemy's longitude is $2^{\circ}$ too small, and the latitude error is similar in Ulugh Beg. This casts much doubt upon the identification of the star as $90 p$, which, however, is not discordant with the description "in dextro crure posteriori." Peters questions whether there is here a variable or a star lost.
526. The identification as 53 is right, but Ptolemy's longitude is $2^{\circ}$ too large. Ulugh Beg is also $\mathrm{I}^{\circ}$ too large. Baily gives latitude $7^{\circ} \mathrm{IO}^{\prime}$.
527. Ptolemy calls this star $\delta \iota \pi \lambda$ oús; Sûfi likewise. The proper motion of Fl . 6I is so great, its distance from Fl. 63 ( $73^{\prime}$ in 1800 ) is reduced to $35^{\prime} .4$ in Ptolemy's time. But could these two together appear double?
528. Peters agrees with Peirce in identifying this as 89 , but the latitude is $\mathrm{I}^{\bullet}$ too far south; Ulugh Beg likewise. Paris 2389, Vat. 1 594, and the Arabs have the correct longitude, $5^{\circ} 0^{\prime}$. Baily has $0^{\circ} 0^{\prime}$.
529. The star is probably $\frac{a^{1}+a^{2}}{2}$ Libræ.
532. Long. Baily has $19^{\circ} 40^{\prime}$, probably a misprint.
541. Ulugh Beg, misled by Sûfi, here probably observed $44 \eta$, but Ptolemy's description does not admit this star. Greek authorities give latitude $3^{\circ} 0^{\prime}$, which is probably an error of $\Gamma=3^{\circ} 0^{\prime}$ for $\Gamma^{\prime}=0^{\circ} 20^{\prime}$. Bod. Arabic 369 and B. M. Reg. 16 have the latitude which has been adopted.
542. Peters identifies the position of this star as Oeltzen's Argelander, 14782, which has been found to be variable. Pickering remarks that it has not been observed brighter than mag. 9.
544. Lat. The Greek manuscripts have $8^{\circ} 30^{\prime}$ and the Arabs $8^{\circ} 10^{\prime}$, which latter is adopted. Baily has $8^{\circ} 30^{\prime}$.
551. The star is $\frac{\omega^{1}+\omega^{2}}{2}$
553. This star, a Scorpii, is one of the six stars designated by Ptolemy as $\dot{u} \pi \dot{\prime} \kappa \iota \rho \dot{\rho} \dot{\rho} \dot{s} ;$ the others being a Bootis, a Tauri, $\beta$ Geminorum, $a$ Orionis, and a Canis Majoris. Questions relating to the color of these stars have been fully discussed by Nallino,* Schiaparelli, $\dagger$ Schjellerup,$\ddagger$ and Knobel, $\S$ including particular reference to the words used in Arabic texts as translation of the Greek. The word $\dot{v} \pi o \dot{\kappa \iota} \rho \dot{\rho} \dot{o} s$ has been erroneously considered as

[^9]signifying red, its true meaning being "yellow, fire or wax-colored, cereus." and in that sense it has been correctly translated in the British Museum Arabic Almagest 7475, where the Greek word is expressed by the word inain shemai, 'wax-like;" but not so in Sûfi and all other Arabic texts. In these the Greek word is rendered by the sentence
 expressed by بكع unknown to Arabs generally, and is not in any Arabic dictionary. All efforts to obtain a solution from scholars, and from the authorities at the Al Azhar Mosque at Cairo, have failed. Causin de Perceval,* speaking of another word used in Arabian Astronomy, says, "On chercherait en vain dans les dictionaires Arabes et Latins l'explication de ce mot, et en général de presque tous les termes d'astronomie Arabe." $\dagger$ Ptolemy's designation of Sirius as $\dot{v} \pi \dot{\prime} \kappa \iota \stackrel{\rho}{\rho} \rho \dot{\rho}$ s has been exhaustively investigated by Schiaparelli and Schjellerup, who have shown the strong improbability of the term "Rubra Canicula" having been correctly applied to that star, or of there being any sound evidence of change in color. Though Suffi omits all reference to the color of Sirius, yet in Bod. 369 and B. M. Reg. 16 the star is described by the same words indicating color as in the other five stars.
555. Lat. The Arabs $6^{\circ}{ }^{\prime} 0^{\prime}$ agrees a little better than the Greek $6^{\circ} 30^{\prime}$ adopted by Baily.
560. Lat. All authorities, except Sûfi and Ulugh Beg, have $18^{\circ} 0^{\prime}$; Sûfi $19^{\circ} 30^{\prime}$. The star, according to Ptolemy's description, should be south of the preceding star and $18^{\circ}$ does not agree at all; $19^{\circ} 0^{\prime}$ has therefore been adopted.
567. Identified correctly by Peters as $\gamma$ Telescopii. Ulugh Beg also observed this star. Ptolemy calls it nebulous. Peters says, "I can not see any nebulosity around it and Sûfi seems to doubt the same." There is, however, close to this star, the cluster N. G. C. 644I, described by Dreyer as "a globular cluster, very bright and pretty large." This seems to be the explanation of Ptolemy designating the object as nebulous.
569. The Greek authorities give the longitude as $25^{\circ} 30^{\prime}$, which Baily has, and the Arabs $29^{\circ} 30^{\prime}$, an error in the Greek of $\boldsymbol{\epsilon}=5$ for $\boldsymbol{\Theta}=9$. The Greek latitude is $I^{\circ} \mathrm{IO}^{\prime}$, and the Arabs $4^{\circ} 10^{\prime}$, a common error in Greek of $A=1$ for $\Delta=4$. In both elements the Arabs are right.
570. Long. All the Greek manuscripts give $9^{\circ} 30^{\prime}$, except Ven. $312,5^{\circ} 30^{\prime}$ (same error as in the preceding note). The Arabs have $4^{\circ} 30^{\prime}$, which is right. The confusion of $\boldsymbol{\Theta}$ or $\boldsymbol{\epsilon}$ for $\Delta=4$ is not easily explicable.
577. The star is $\frac{\nu^{1}+\nu^{2}}{2}$. Ptolemy describes it as $\nu \epsilon \varphi \epsilon \lambda 0 \epsilon \iota \delta \dot{\eta} s \kappa \alpha \iota \delta \iota \pi \lambda o u$. There are several small stars close.
578. Fl. $37 \xi^{2}$ agrees better for position and is brighter than $\xi^{1}$.

584 and 585 . Ptolemy's large errors in longitude appear also in Ulugh Beg. Baily gives longitude of 584 as $25^{\circ} 20^{\prime}$. There are no other stars corresponding.
587. Long. The Greek give longitude $22^{\circ} 40^{\prime}$ and the Arabs $22^{\circ} 20^{\prime}$, which latter is to be preferred. It is probable that $47 \chi^{1}$ and $49 \chi^{3}$ were observed as one mass.
592. Lat. The latitude is $I^{\circ}$ too far south.
593. Long. Ptolemy's longitude is $2^{\circ}$ too small. Sûfi remarks the error; Ulugh Beg is right.
596. Long. All the Greek authorities have $23^{\circ} 50^{\prime}$ and the Arabs $26^{\circ} 50^{\prime}$-the latter is

[^10]adopted. Peters had $24^{\circ} 50^{\prime}$ from Halley. The latitude in all the Greeks and some Arabs is $26^{\circ} 0^{\prime}$. The only manuscript that gives the right latitude is B . M. Arabic $7475,20^{\circ} 10^{\prime}$. In the Greek there is an error of Ks for $\mathrm{Ks}^{\prime}$.
597. Long. Baily has $27^{\circ} 20^{\prime}$.
604. Long. All authorities give the longitude either $9^{\circ} 0^{\prime}$ or $5^{\circ} 0^{\prime}$; similar error in the Greek, of which several examples have been given. Peters' adopted longitude of $6^{\circ} 0^{\prime}$ is mere conjecture. It is more probable that the original was $5^{\circ} 0^{\prime}$ and this was the opinion of Halley. Peters remarks that the proper motion of $2 \xi^{2}$ would bring the stars $\xi^{1}$ and $\xi^{2}$ quite close together in Ptolemy's time, only $5^{\prime} \cdot 5$ apart, and that it was the combination of these stars that was observed.
609. As $\tau^{2}$ is a little larger it was more likely to be the star observed, but perhaps $\frac{\tau^{1}+\tau^{2}}{2}$
610. Lat. Baily has $0^{\circ} 10^{\prime}$ from Trapezuntius. The Arabs have $0^{\circ} 50^{\prime}$, which is adopted.
6II,612,613. See Baily's note on the confusion of these stars in different manuscripts. The description adopted agrees with Baily and Gerard of Cremona. Manitius adopts a different order.
613. Ptolemy's longitude is $\mathrm{I}^{\circ}$ too large.

6I 5. Baily identifies as 35 Capricorni, mag. 6.o. Peters adopts $36 b$, mag. 4.5, as being larger and more probable.
624. Liechtenstein and Sûfi erroneously designate the latitude north.
625. Ptolemy's longitude is too large.
626. Table of Collations shows that four Greek authorities (as well as Grynæus and Halma) have the erroneous longitude $20^{\circ} 40^{\prime}$.
634. 13 $\nu$ was the star observed by Ptolemy, whose longitude, however, needs a correction of $+2^{\circ}$.
635. The latitude appears to be $\mathrm{I}^{\circ}$ too small, though it agrees with Ulugh Beg.
642. Baily adopts latitude $2^{\circ} 10^{\prime}$, which is erroneous.
645. Most of the authorities have latitude $4^{\circ} \mathrm{o}^{\prime}$. Paris 2389 is correct; error of $\Delta=4^{\circ} \mathrm{o}^{\prime}$ for $\Delta^{\prime}=0^{\circ} 15^{\prime}$. Peters identifies as $38 e$, Baily as $37 e^{1}$. Sûfi, misled by the erroneous latitude $4^{\circ} 0^{\prime}$, observed Fl. 30. Manitius makes the latitude south.
649. Sûfis observations point to $68 g^{2}$ as the star which was observed by Ulugh Beg. Baily's identification as $59 v$ supposes an error of $3^{\circ}$ in Ptolemy's longitude.
65 I and 652 . Peters identifies 65 I as Fl. 63 K , but longitude and latitude are largely in error. The description of 651 is "Antecedens duarum quæ sunt in ipso aquæ fluxu a manu'"; and the description of the following star, 652, is "Quæ istam adhuc sequitur." The latter star is correctly identified as Fl. $73 \lambda$. The star which precedes it and forms the pair referred to by Ptolemy is perhaps Fl. 67, though very uncertain, and it is smaller than 63 k . In the case of 63 k we have errors, longitude $-115^{\prime}$, latitude $+136^{\prime}$, and for Fl. 67 the errors are longitude $-106^{\prime}$, latitude $-5 \mathbf{1}^{\prime}$. Baily identifies 65 I as 67 and adds that a correction of $+2^{\circ}$ should be made to the longitude. Schjellerup identifies as Fl. 67. Sûfi omits 651 altogether.
657. The position is equally good for either $93 \psi^{2}$ or $95 \psi^{3}$. The first is the larger star. 658. The star is probably Fl. 94. Sûfi seems to have observed Fl. 97, which gives errors of longitude - $113^{\prime}$, and latitude $-106^{\prime}$, and is smaller than 94. Ulugh Beg observed 94. All authorities give longitude $20^{\circ} 50^{\prime}$, which is $3^{\circ}$ too large. Upon this assumption Peters adopts $17^{\circ} 50^{\prime}$.
659, 660. Baily gives the longitude of 659 as $22^{\circ} 20^{\prime}$. There is no doubt that Ptolemy and Ulugh Beg observed $\omega^{1}$ and $\omega^{2}$. It is curious that Sûfi remarks that
near one of these stars there is a star of mag. 6 , which makes it double. Peters says it can hardly be the variable $R$ Aquarii, which is $I^{\circ}$ distant. It is probable that Sûfi really observed R at its maximum. The positions of $\omega^{2}$ and R for 1875 are:

\[

\]

661. It is probable that the two stars $A^{1}$ and $A^{2}$ were observed as one mass $\frac{A^{1}+A^{2}}{2}$.
662. Baily identifies as $106 i^{1}$, but $108 i^{3}$ agrees better; it is also described by Sûfi. Ulugh Beg seems to have observed 107.
665 and 666. The longitudes and latitudes are transposed in nearly all the manuscripts.
663. Lat. Peters' latitude, $16^{\circ} 15^{\prime}$, is a conjecture; there is no authority for it, and there is no ready explanation of confusion in the Greek letters for $14^{\circ} 45^{\prime}$ or $14^{\circ} 50^{\prime}$ and $16^{\circ} 15^{\prime}$.
664. Long. Baily has $12^{\circ} 20^{\prime}$.
665. This is the same star as No. IOII.
666. Long. Baily has $20^{\circ} 10^{\prime}$.
667. Longitude $I^{\circ}$ too large, latitude $I^{\circ}$ too far south.
668. Longitude adopted from Paris 2389, one reading, and Arabs. Baily has $23^{\circ} 20^{\prime}$. Latitude $\mathrm{I}^{\circ}$ too far south.
669. Here Ulugh Beg has the south latitude too small.
670. Longitude of the Arabs adopted as more correct. Baily has $28^{\circ} 20^{\prime}$.
671. Lat. Baily has $I^{\circ} 45^{\prime}$, which is found only in Trapezuntius, Schreckenfuchs, and the Crawford manuscript of Gerard of Cremona.
672. Longitude of Arabs $0^{\circ} 20^{\prime}$ is better than the Greek $0^{\circ} 40^{\prime}$, which Baily adopts.
673. Peters identifies as the combination of 93, mag. 5.3, and 94, mag. 5.6, and adds that these two stars viewed as one mass would appear about mag. 4.7, so that the mean differences should be taken.
702 to 704. These are the stars observed by Ptolemy and described by Sûfi, but the positions are in error, as was noted by Sûfi. Manitius identifies 704 as $\chi$, but though the position would suit, it is discordant with the description. Peters considered there was no doubt that No. 707 is correctly identified as $\chi$, though the longitude is $2^{\circ}$ too large.
716, 717. Baily gives the longitude of 716 as $10^{\circ} 20^{\prime}$. These two stars present much difficulty. It is suggested that 716 may be either $78 \nu$, or $73 \xi^{2}$, but both give large errors in both elements. No star harmonizes with Ptolemy's position of 717. Schjellerup and Manitius identify as $\mu$ Ceti, but this star is more probably 374, Ptolemy's 13th star in Aries. The question of these two stars remains undecided.

|  |  |  |  | Positi | D. | 100 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Long. | Lat. |  | Long. | La |  |
|  |  |  |  |  |  |  |
| 716. | 1010 | -810 | $78 \nu$ | 1158 | -9 | 21 |
|  |  |  | $73 \xi^{2}$ | 112 | -6 |  |
| 717. | 1240 | -6 20 | $87 \mu$ | 1521 | -5 |  |

726. The latitude $15^{\circ} 20^{\prime}$ of the Arabs has been adopted in preference to $15^{\circ} 40^{\prime}$ of the Greek, which Baily has.
728 to 73 I . The identification of these 4 stars seems correct; they accord with the description. Longitude and latitude of 729 are largely in error. Ulugh Beg's latitude also in error.
727. Lat. The Greek manuscripts all have $16^{\circ} 30^{\prime}$, with the exception of one reading of Paris 2389, and Cod. Ven. 303, which are $13^{\circ} 30^{\prime}$. Sûfi and the Arabs have $13^{\circ} 50^{\prime}$, or $18^{\circ} 50^{\prime}$, which are equivalent by the common error of $\tau=8$ and $\tau=3$. Baily remarks upon the error of $3^{\circ}$ in the Greek authorities. Ptolemy describes this star as $\nu \in \varphi \in \lambda=\epsilon \iota \delta \eta^{\prime} s$, probably from it making with $\varphi^{1}$ and $\varphi^{2}$ Orionis a small cluster.
728. Ptolemy's longitude seems $\mathrm{I}^{\circ}$ too large.
729. Ptolemy's longitude is too small, also when compared with Ulugh Beg.
 LL 11884 being near and south of $\xi$.
730. Ptolemy's longitude $I^{\circ}$ too large.

742 and 743. As Gore has correctly pointed out, the description of these stars should be reversed.
748. Lat. Baily has $20^{\circ} 10^{\prime}$.
752. Baily denotes this as 6 g . Peters identifies as $9 o^{2}$. The same deviations in longitude and latitude are found here as in Ulugh Beg. Baily's star 6 g. does not agree at all.
763. Lat. The Greek $28^{\circ} 20^{\prime}$, which Baily has; the Arabs $28^{\circ} 40^{\prime}$, which is adopted.
767. Long. The Greek $26^{\circ} 30^{\prime}$, except Vienna 14, the Arabs $26^{\circ} 10^{\prime}$, adopted, but longitude still too large.
774. Long. All the authorities have $48^{\circ} 0^{\prime}$, which is $I^{\circ}$ too large, also in comparison with Ulugh Beg.
775. Long. Paris 2394 has $i \delta u^{\prime}$ in which the " $u$ " is an old cursive form of $\beta$, and in this manuscript it would signify $14^{\circ} 40^{\prime}$. Grynæus has $\delta \delta \epsilon^{\prime}=14^{\circ} 12^{\prime}$.
777. Long. Several Greek manuscripts have $16^{\circ} 0^{\prime}$ for $10^{\circ} 10^{\prime}$; error of is for $1 s^{\prime}$. Baily has $18^{\circ} 20^{\prime}$, for which there is no authority.
778. Lat. Halma has $25^{\circ} 20^{\prime}$, which he has taken from Halley.
779. Baily has longitude $3^{\circ} 30^{\prime}$, and latitude $28^{\circ} 30^{\prime}$. Peirce considers the star to be 98 Heis. Peters agrees with Baily and Schjellerup in identifying as $400^{2}$.
78 I . Lat. All authorities give $32^{\circ} 50^{\prime}$. Halma gives $33^{\circ} 10^{\prime}$, which he has taken from Halley.
786. It is not possible to decide whether the star is $\rho^{2}$ or $\rho^{3}$. Ptolemy observed them as one mass.
787. Lat. The Greek authorities give $23^{\circ} 30^{\prime}$, while the Arabs have $23^{\circ} 50^{\prime}$. Halma alone has $24^{\circ} 30^{\prime}$, taken from Halley, and Baily adopts it. Peters did not notice the extracts from Halley made by Halma and Baily, and which he had adopted. In the present case the reading of the Arabs is taken.
788. Flamsteed remarks that a star noted by Ptolemy as of the 4th magnitude, and which is the 17th of the constellation Eridanus in his catalogue, could not be found now. About the position of the star all editions agree; it is the same in all existing manuscripts, both Greek and Arabic, and was the same also in the manuscript used by Sûf. Sûfi says of this star: "The 17 th , which precedes the 16 th , is the last of the four, and at the western extremity of the series, near the four stars situated on the breast of Cetus. It is of the smaller ones of the 5th mag., almost of the 6th, and there is between it and the nearest star of the four situated on the breast of Cetus, that is, the ioth of Cetus, less than one 'coudée.'" Bode takes the star to be $\sigma$ Eridani (Bayer and Ideler likewise), but says that since Flamsteed it is wanting upon all star charts and in the sky. Manitius takes it to be $\eta$, and the preceding star $\rho^{3}$. According to Ptolemy's difference with $\eta$ Eridani, the star could be Heis 10, $6.7 \mathrm{mag} .=\mathrm{W}$. B. $2^{\mathrm{h}} 788$. According to Sûfis description, the star seems to be nearer to $\epsilon$ Ceti (moins d'une coudée) than to $\eta$ Eridani. He puts the distance between $\rho$ and $\eta$ Eridani as one coudée.

The following table shows the comparison between Ptolemy, Ulugh Beg, and computed positions, for A. D. 100, assuming the star to be W. B. $2^{\mathrm{h}} 788$ :

| Ptolemy's star. | Ptolemy. |  |  | Ulugh Beg reduced. |  | Name. | Computed. |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Mag. | Long. | Lat. | Long. | Lat. |  | Long. | Lat. |
|  |  | - , | - , | - , | - , |  | $\bigcirc 1$ | - , |
| 16 Eridani. | 3 | 1210 | -23 30 | 1237 | -24 35 | $\eta$ Eridani.... | 1214 | -24 41 |
| 17 Eridani. | 4 | 1030 | -2315 | II 35 | -2417 | W. B. $2^{\text {b }} 788$. | 11 | -24 56 |
| Io Ceti | 4 | 640 | $-2510$ | 746 | -26 20 | $\epsilon$ Ceti | 648 | -26 7 |

We get the differences:

|  | 17- $\eta$ Eridani. |  | 17-6 Ceti. |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Long. | Lat. | Long. | Lat. |
|  | , | , | - , | $\bigcirc{ }^{\circ}$, |
| Ptolemy . | -140 | +15 | +350 | +155 |
| Ulugh Beg. . | $\begin{array}{ll}-1 & 2 \\ -1 & 7\end{array}$ | +18 | +349 +349 | +23 |
| Computed.. | -1 7 | $-15$ | +419 | +1 11 |

The star W. B. $2^{\mathrm{h}} 788$ is therefore the nearest. Ptolemy calls 17 Eridani of the 4 th magnitude, but Sûfi of the 5th magnitude, small, almost the 6th. In Harvard R. Photometry $\eta$ Eridani is 4.0 mag. and $\epsilon$ Ceti 5.0 mag. The Uranometria Argentina gives the magnitude of W. B. $2^{\mathrm{h}} 788$ as 6.4 . In the following chart the position of W. B. $2^{\mathrm{h}} 788$ is marked by a + .

Fig. 4.-Chart of the Position of Ptolemy's Star 17 Eridani.
798. All the Greek manuscripts have the latitude erroneously $53^{\circ} 20^{\prime}$; the Arabs are right. The longitudes of this and the following star are $\mathrm{I}^{\circ}$ too large, also by comparison with Ulugh Beg.
798 to 804. There is some confusion in the nomenclature of these stars, which are named $v^{1}$ to $v^{7}$, but in different order. The designations given by Peters are those of Taylor's Madras Catalogue, the maps of the S. D. U. K. and Proctor's Atlas. The reverse order is adopted in the Uranometria Argentina, Cape Catalogues, by Peirce, Houzeau, Schjellerup, and Manitius.
802. The position agrees better with III 202, though Ulugh Beg observed III 189.
803. Ptolemy's position agrees better with Lac. g, though Ulugh Beg observed Lac. $f$.
804. Ptolemy's latitude is $2^{\circ}$ or $3^{\circ}$ too small. Sûf's description of Ptolemy's $31-33$ identifies them as Lacaille $g$, $f$, and $h$.
805. Several Greek authorities give the longitude $7^{\circ} 30^{\prime}$; one reading of Paris 2389 and all the Arabs have $0^{\circ}$ ro'. Halma gives as a variant $27^{\circ} 30^{\prime}$, which he has clearly taken from Halley. In Paris 2394 the degrees of longitude are represented by an old cursive form of the letter $\xi$ and so the longitude is $60^{\circ} 40^{\prime}$; Grynæus has the longitude $60^{\circ} 40^{\prime}$, precisely the same. Baily gives Grynæus erroneously as $7^{\circ} 4^{\prime}$. All authorities, even Sûfi, designate the star as of the first magnitude. The nearest star of the first magnitude is $a$ Eridani, which could not have been seen by Ptolemy and Suffi. The position is near the place of $\theta$ Eridani. Peters suggests that Ptolemy's place may be a compilation from inaccurate sources; he remarks that Sûfi clearly considered $\theta$, and not $a$ Eridani. The computed positions of the two stars for A. D. 100 are:

$$
\begin{aligned}
& \text { Long. Lat. }
\end{aligned}
$$

It is surmised that there is a large error in Ptolemy's position or that the magnitude has changed. Peters, Baily, Peirce, and Manitius identify the star as $\theta$, Halma and Schjellerup as a Eridani; Delambre adopts Halley's longitude, $27^{\circ} 30^{\prime}$, and adds in a note "La dernière brillante du Fleuve ne peut être que la dernière de l'eau du Verseau, qui s'appelle aussi le Fleuve ou le Nil." $\theta$ Eridani shows no signs of variability; it is therefore highly improbable that its magnitude has changed from a first to a third magnitude star. All Almagests give mag. 1 , and it is most probable that in a very ancient manuscript the delta $=4$ was erroneously taken to be an alpha $=1$, of which the present investigation shows numerous examples. Thus Ptolemy's magnitude should be 4. A corresponding error is found in the Bodleian Greek Almagest, where the magnitude of Sirius is given as 4 instead of 1 .
806. Long. Baily adopts $19^{\circ} 0^{\prime}$, but the authority for $19^{\circ} 40^{\prime}$ is much stronger.
813. All Greek authorities give longitude $24^{\circ} 50^{\prime}$; the Arabs (Bod. 369, B. M. Reg. 16, Laur. 156, and Sûfi) have $24^{\circ} 20^{\prime}$, which is better and has been adopted.
822. All the manuscripts have longitude $25^{\circ} 20^{\prime}$, which is erroneous. Sûfi has $20^{\circ} 20^{\prime}$, which is right.
833. All authorities give longitude $23^{\circ} 0^{\prime}$. Peters suggests that it should be $21^{\circ} 0^{\prime}$ and it would then compare with Ulugh Beg.
836. Peters identifies as 22 Monocerotis (4.1 mag.) in preference to 19 Monocerotis ( 4.9 mag.); adopted by Baily and followed by Manitius, though the position of the former is more largely in error than the latter.
837. All authorities give longitude $10^{\circ} 0^{\prime}$, which is $3^{\circ}$ too large. Ulugh Beg is right. Peters has adopted $7^{\circ} 0^{\prime}$.
843. Lat. The Greek manuscripts have $59^{\circ} 50^{\prime}$, and the Arabs $59^{\circ} 30^{\prime}$, which is better.
848. Long. The Arabs have $29^{\circ} 10^{\prime}$, which is better than $29^{\circ} 30^{\prime}$, as in the Greek and Baily.
849. The nomenclature of the stars in Argo is very confusing. The Index in Harvard Annals, vol. 50 , has been followed as far as possible.
855. Latitude is variously given as $49^{\circ} \mathrm{I} 5^{\prime}, 49^{\circ} 30^{\prime}, 49^{\circ} 45^{\prime}$, and $49^{\circ} 50^{\prime} ; 49^{\circ} 30^{\prime}$ seems to have the most authority. Baily adopts $49^{\circ} 15^{\prime}$.
856. Latitude $49^{\circ} 30^{\prime}$ of the Arabs is preferable to $49^{\circ} 50^{\prime}$ of the Greeks, which Baily takes.
859. Sûfi's description leads upon Lacaille 2834. Mag. 5.3, U. A., the computed position of which is longitude $96^{\circ} 7^{\prime}$, latitude $-52^{\circ} 6^{\prime}$, giving errors of longitude $+127^{\prime}$ and latitude $+54^{\prime}$.
86r. Lat. Baily gives $56^{\circ} 30^{\prime}$, for which the only authority found is the Crawford Codex.
865. Lat. Greek $58^{\circ} 40^{\prime}$, Arabs $58^{\circ} 20^{\prime}$, the latter adopted; but this is not Ptolemy's star, whose position accords better with the group VII 102, 108, and 113 .
867. Peters remarks that there is no star in the position described by Sûf.
868. Long. Baily adopts $23^{\circ} 10^{\prime}$.
869. Lat. Greek $57^{\circ} 40^{\prime}$, and Arabs $57^{\circ} \mathrm{o}^{\prime}$.
870. Peters identifies this star as Lacaille 3580, mag. 5.8, but questions whether it is not too small. There is no star in the place described by Sûfi.
875. Lat. Baily adopts $51^{\circ} 4^{\prime}$.
879. Long. $14^{\circ} 10^{\prime}$ has much better authority than $15^{\circ} 10^{\prime}$ given by Baily.
880. Lat. All authorities agree, but it is $I^{\circ}$ too far south.
882. Long. This is $2^{\circ}$ too small, also by comparison with Ulugh Beg. Suff's description leads to Lac. 3022, which does not agree at all; longitude $113^{\circ} 2^{\prime}$, latitude $-65^{\circ} 24^{\prime}$.
884. Ptolemy's longitude wrong. There is no other star here larger than mag. 4.
885. The identification of this star is probably correct, but longitude is $3^{\circ}$ in error.
886. The identification right, longitude too small.
887. Identified as $f$ Carinæ, with which the position agrees, but the magnitude is 4.6 , which is entirely discordant with Ptolemy's mag. 2. Baily adopts $\iota$ Argūs, but this involves an error of $12^{\circ}$ in longitude and $3^{\circ}$ in latitude. Schjellerup also adopts $\iota$ Argūs, the magnitude of which is 2.2 (H. R.). Is $f$ Carinx variable?
Suff's description of the latter half of the constellation Argo is accurate and agrees with the sky (except Nos. 19 and 22, where there are no stars to be seen now). But the positions of Ptolemy and of Ulugh Beg do not agree with Sûfi in many places.
889. Lat. Baily has $65^{\circ} 15^{\prime}$, for which there is far less authority than $62^{\circ} 15^{\prime}$.
895. Lat. Baily has $13^{\circ} 40^{\prime}$.
897. Lat. Paris 2389 confirms the Arabs' $14^{\circ} 45^{\prime}$, which agrees better than $14^{\circ} 15^{\prime}$.
898. The latitude $12^{\circ} \mathrm{O}^{\prime}$ of the Arabs agrees better than $12^{\circ} 15^{\prime}$ of the Greek.
899. Sûf has latitude $14^{\circ} 40^{\prime}$, an error in the degrees of $\Delta$ for $A$.
900. Sûfi has the erroneous latitude of $19^{\circ} 20^{\prime}$.
904. The identification of this star as $\mathrm{Ll} .18657=$ W. B. $9^{\mathrm{h}} 439$ agrees better than Baily's star Fl. 28 A. Manitius gives it as Fl. 29.
905. All authorities have latitude $20^{\circ} 30^{\prime}$, which should be $23^{\circ} \mathrm{O}^{\prime}$. Probably it was $20^{\circ} 20^{\prime}$, with the common mistake of $\mathrm{K}^{\prime}$ for $\mathrm{K} \Gamma$.
908. All Greeks have latitude $26^{\circ} \mathrm{I} 5^{\prime}$, which is erroneous. The Arabs have it correctly, $23^{\circ} 15^{\prime}$. Baily adopts $23^{\circ} 35^{\prime}$ from Liechtenstein, which is an obvious mistake of Gerard of Cremona.
909. Lat. The correct latitude of $24^{\circ} 40^{\prime}$ is found in the Greek manuscripts Paris 2389, 2390, Ven. 3I2, Vat. Reg. 90, and the Arabs. All the others, including variants in Paris 2389, 2390, and Ven. $3 \mathbf{1 2}$, have $45^{\circ} 30^{\prime}$, or $49^{\circ} 30^{\prime}$ ( $\boldsymbol{\theta}$ for $\boldsymbol{\epsilon}$ ). It is possible that in a very ancient manuscript the latitude of a star in Argo was copied inadvertently into Hydra.
910. Ptolemy's longitude is $I^{\circ}$ too small, also in comparison with Ulugh Beg.
914. Longitude $I^{\circ}$ too large, also by comparison with Ulugh Beg.
918. Ptolemy's longitude and latitude quite erroneous. B. M. Sloane 2795 gives latitude $13^{\circ} 40^{\prime}$, but probably copied from the previous star. Ulugh Beg is right.
920. All authorities give latitude $16^{\circ} 0^{\prime}$, probably an error of $I s=16^{\circ} 0^{\prime}$ for $1 s^{\prime}=10^{\circ} 10^{\prime}$, which is adopted. Ulugh Beg's errors are similar. The position accords best with 24 Sextantis, longitude $131^{\circ} 36^{\prime}$, latitude $-10^{\circ} 18^{\prime}$, but that star is only mag. 6.7 (U. A.). Sûfi certainly describes 15 a Sextantis (mag. 4.5 ), and this star is adopted by Schjellerup and Peirce, but it assumes an error of $3^{\circ}$ in the longitude. To all appearance there was here a star seen by Ptolemy, Sûfi, and Ulugh Beg that now is not visible or shining prominently. Manitius identifies as $\delta$ Sextantis.
927. The longitude of the Arabs has been adopted. Baily gives $1^{\circ} 20^{\prime}$.
940. The large proper motion of $\theta$ Centauri, amounting in 1700 years to $28^{\prime}$ in latitude, increases the discordance with Ptolemy's latitude, which is $I^{\circ}$ too far south.
956. Peters identifies as Lac. $5390 f$ as Baily; Schjellerup as $\xi$. Sûficalls the star double, which clearly refers to $\xi^{1}$ and $\xi^{2}$, but the position of $\xi^{1}$ (longitude $190^{\circ} 28^{\prime}$, latitude $38^{\circ} 42^{\prime}$ ) deviates more than 5390 f .
962 to 971 . There are very large errors in the longitude and latitude of these stars common to all the manuscripts. Some of the errors may be accidental, or due to the scribe, but the general inference is that the observations were made by different observers. (See note to 494-496.)
964. Sûfi finds no star visible near Ptolemy's place. It should be, as Sûfi remarks, of mag. 3, following upon the 29th star (No. 963). The nearest star would be Lacaille 5632 , but the magnitude is $5 \cdot 4$.
969. Long. Peters considered that there was here the not uncommon error in the Arabic of 8 for 3 , which would make the longitude $213^{\circ} 20^{\prime}$, but the resulting error is equally large, though of a different sign.
971. Cod. Vienna 14 and Cod. Vat. Reg. 90 give the longitude as $1 I^{\circ} 40^{\prime}$; all other Greek sources, as well as the Arabs, give $14^{\circ} 40^{\prime}$, an error of $A$ for $\Delta$. The adoption of $1 I^{\circ} 40^{\prime}$ would give a more consistent error in Ptolemy's longitude $=+2^{\circ} 43^{\prime}$.
979 to 981 . The errors in longitudes of these three stars differ from all others in the constellation Lupus in that they have a minus sign. From this Peters inferred that they may have been derived from a different observer.
982. Long. The Greeks $22^{\circ} 0^{\prime}$ and the Arabs $20^{\circ} 20^{\prime}$. Peters corrects it to $26^{\circ} 0^{\prime}$. The identification of this star presents considerable difficulty. The description states "Australis de tribus quæ sunt in extrema cauda." The following star, 983 , correctly identified as $\iota$ Lupi, is "Media ipsarum," and the next, 984, also correctly identified as $\tau^{1}$ and $\tau^{2}$, is "Borealis ipsarum." Peters first suggested that the star was Lac. 5209, but this is in Crux and a long way from the described position. Sûfi could not find the star and of course it is omitted by Ulugh Beg. Peters finally adopted Lac. $6003 \rho$, which, assuming an error of $4^{\circ}$ in longitude, would agree well; but the position is quite discordant with the description. Manitius identifies $982-984$ as $\sigma, \rho$, and a Lupi, the positions of which would accord with the description, but involve very large errors in longitude; moreover, a Lupi
seems well identified as Ptolemy's second star in Lupus. Baily's identification for the three stars is Lac. $1201 \tau, 1215 \iota$, and $1209 \kappa$ ( $1201=\iota$ and $1209=\tau^{1}$ ). It must remain a question whether there is here a variable or a lost star.
983. Long. Baily has $24^{\circ} 50^{\prime}$.
989. Peters' identification agrees with Baily and Manitius. The longitude and latitude of the Arabs has been adopted. Baily gives longitude $27^{\circ} 10^{\prime}$, latitude II ${ }^{\circ} 5^{\prime}$.
990. All authorities give longitude $26^{\circ} 30^{\prime}$, except B. M. Arabic 7475, which has $27^{\circ} 30^{\prime}$. Halma has $27^{\circ} 30^{\prime}$, which would be much better. Peters questions his authority. There is no doubt that Halma took it from Halley's edition. Ulugh Beg's longitude is also $\mathrm{r}^{\circ}$ too small. The latitudes of the last three stars in Lupus are $I^{\circ}$ too far north.
992. Several Greek authorities have longitude $3^{\circ} 0^{\prime}$; the Arabs $0^{\circ} 20^{\prime}$; the former is adopted-an error of $\Gamma^{\prime}=0^{\circ} 20^{\prime}$ for $\Gamma=3^{\circ} 0^{\prime}$. Baily adopts $3^{\circ} 10^{\prime}$.
993. Long. Baily adopts $26^{\circ} 20^{\prime}$.
994. Lat. With the exception of Ven. 311 , Laur. 1, and Laur. 6, all Greek codices, as well as Grynæus and Halma, have latitude $1^{\circ} 30^{\prime}$ instead of $30^{\circ} 30^{\prime}$. An error of $A=1^{\circ}$ for $\Lambda=30^{\circ}$.
997. Latitude $34^{\circ} 0^{\prime}$ adopted from the Arabs. Baily has $34^{\circ} 15^{\prime}$. Peters agrees with Schjellerup in the identification of the stars in Ara. Baily identifies in this order: $\gamma, \epsilon, \delta, a, \beta, \eta, \theta$. There is a large error in all the longitudes, averaging $2^{\circ} 18^{\prime}$ too small. These errors resemble those already referred to under 494-496, and 962-97I.
998. Peters identifies as $\frac{\delta^{1}+\delta^{2}}{2}$ Telescopii, as it agrees better in longitude, but remarks that it is not probable that a Telescopii should have been omitted.
1000. Baily identifies as $1566 \zeta$, which star Peters identifies in No. ıoor.
1001. Baily identifies as $\beta$. Peters considers $\beta$ to be 1003 .
1004. Longitude $16^{\circ} 50^{\prime}$ adopted from Cod. Vat. 1594, and the Arabs. Baily has $16^{\circ} 20^{\prime}$.
1008. Baily has latitude $15^{\circ} 50^{\prime}$, for which there is no authority; it is probably a misprint.
1009. Identified as Lac. 7748, which agrees better with Ulugh Beg's observations than Lac. $7758=\mathrm{I} 528 \kappa$, identified by Baily, Schjellerup, and Manitius. Sûf's description refers clearly to Lac. 7748.
IOII. This is the same star as No. 670 . Baily gives latitude $23^{\prime} 0^{\prime}$ ', though for No. 670 he has $20^{\circ} 20^{\prime}$.
IOI3 and IOI 5. Vatican Reg. 90 gives the longitudes as $30^{\circ} 10^{\prime}$ and $30^{\circ} 20^{\prime}$, respectively. Probably the original degrees were $\Delta=4$, then erroneously $A=1$, then erroneously $\Lambda=30$.
1017. Peters remarks that longitude $2^{\circ} 10^{\prime}$, adopted by Halma, would be much better, but there is no authority. Here again Halma has taken the longitude from Halley, which, as already pointed out, is not a collation of any manuscripts, but an edition in which many errors are corrected by computation.
1023. Baily has taken the Greek description of this star from Grynæus, which is identical with Paris 2389 ; both are erroneous, as they omit the word $\tau \rho \iota \bar{\omega} \nu$. Vatican 1594 is correct.
1023 to 1028. Peters identifies these six stars, forming the informate of Piscis Austrinus, as Lacaille 8579, 8639, 8761, 8685, 8731, and 8689. The identifications are not open to much doubt, but there are large errors in the coördinates of the six stars, averaging in longitude $+\mathrm{r}^{\circ} 2 \mathrm{I}^{\prime}$, and in latitude $+6^{\circ} 36^{\prime}$. Upon this identification 1028 is the same star as 613 .

## THE STAR MAGNITUDES.

The magnitudes of the stars in the catalogue are those deduced as most probable from consideration of the Table of Star Magnitudes (pp. 122-143), besides many other authorities mentioned in the notes.

The magnitudes in the Greek codices generally agree very well. Comparing the two oldest Greek codices, Paris 2389 and Vatican 1594, twelve differences are found, of which Paris 2389 is correct in ten and Vatican 5994 in two cases. Comparing Vatican 1594 with Venice 313, only 4 differences are noted. Comparing Paris 2389 with the Arabic codex, British Museum Reg. 16, there are 35 differences, of which Paris 2389 is correct in 21 and B. M. Reg. 16 correct in 13 cases, with one case in which both are probably wrong. The Arabic codex, B. M. Reg. 16, is particularly valuable from the great care with which it has been written. In all series of stars of the same magnitude, the magnitudes of the first and last only are written-a method which avoids many mistakes.

The magnitudes adopted in the catalogue differ from those in Paris 2389 in the following 14 stars: Baily, Nos. 128, 129, 130, 154, $211,352,480,509,576,736,764$, 765,824 , and 885 .

It will be seen in Table VIII that Dr. Peters has adopted magnitudes for some stars which differ from all manuscripts of the Almagest yet examined, and for which no authority can be found. In a note on one of his collations, he says that he has "inserted the revised magnitudes of the Paris Codex 2389, besides several notes on the stars in my copy of Baily's Ptolemy" (Mems. R. A. S., Vol. XIII), but unfortunately this volume can not be found.

The magnitudes in Ptolemy's catalogue have been fully discussed by Prof. E. C. Pickering in H. A., Vol. XIV, Part II. In this memoir he has reduced Ptolemy's magnitudes to the photometric scale of the Harvard Photometry, and arrives at the accompanying photometric values:

| Ptolemy <br> magnitude. | Photometric <br> magnitude. | Ptolemy <br> magnitude. | Photometric <br> magnitude. |
| :---: | :---: | :---: | :---: |
|  | 0.5 |  |  |
| I | 1.2 | $3-4$ | 3.8 |
| I-2 | 1.2 | $4-3$ | 3.8 |
| $2-1$ | 2.1 | 4 | 4.4 |
| 2 | 2.6 | $4-5$ | 4.6 |
| $2-3$ | 2.7 | $5-4$ | 4.7 |
| $3-2$ | 3.3 | 6 | 5.0 |
| 3 |  |  | 5.4 |

In the following table of whole magnitudes 2 to 6 (Table VII), a rather larger number of stars is employed and the magnitudes are based on the Harvard Revised Photometry. The corresponding figures from H. A., Vol. XIV, are appended in italics. It will be seen that the results do not suggest any material difference from those obtained by Professor Pickering in the above investigation.

Table VII.

| Ptolemy magnitude. | No. of stars. |  |  |  | Mean magnitudes. |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | North. | Zodiac. | South. | All. | North. | Zodiac. | South. | All. |
| 2 | 11 | 6 | 12 | 29 | 2.20 | 2.10 | 2.14 | 2.14 |
|  | 12 | 6 | 7 | 25 | 2.04 | I. 95 | 2.23 | 2.07 |
| 3 | 63 | 52 | 46 | 161 | 3.22 | 3.24 | $3 \cdot 35$ | 3.27 |
|  | 58 | 44 | 34 | 136 | 3.28 | $3 \cdot 31$ | $3 \cdot 36$ | $3 \cdot 31$ |
| 4 | 121 | 100 | 111 | 332 | 4.32 | 4.45 | 4.30 | $4 \cdot 36$ |
|  | 119 | 105 | 75 | 299 | 4.33 | 4.48 | 4.32 | $4 \cdot 38$ |
| 5 | 48 | 95 | 38 | 181 | 4.84 | 5.08 | 4.64 | 4.85 |
|  | 40 | 82 | r6 | r38 | 4.81 | 5.04 | 4.82 | 4.95 |
| 6 | 13 | 24 | 8 | 45 | 5.27 | 5.36 | 5.22 | 5.28 |
|  | 9 | 25 | 4 | 38 | $5 \cdot 46$ | $5 \cdot 38$ | 5.18 | $5 \cdot 3^{8}$ |

In Table VIII the first column gives the number of the star in Baily's Ptolemy; the second column the name of the star; the third gives the magnitudes assigned by Dr. Peters, an asterisk ( ${ }^{*}$ ) indicating those which differ from the magnitudes adopted in the catalogue; the next three columns give the magnitudes in the Greek codices, Paris 2389, Vatican 1594, and Venice 313; the following column gives the magnitudes adopted by Manitius from the several Greek manuscripts he examined; then follow the magnitudes in three Arabic codices, British Museum Reg. 16, British Museum 7475, and Bodleian 369; and in the last column is given the magnitudes in the Harvard Revised Photometry; for double stars the combined magnitude is given.

The Notes on pp. 144-150 give the variants from the adopted magnitudes, in the Greek codices, Paris 2389, Vatican 1594, Vatican 1038, Venice manuscripts 302, 310,312 , and 313, and Laurentian 48; the Latin codex Laurentian 6, and the three Arabic codices, British Museum Reg. 16 and 7475, and Bodleian 369. The magnitudes in the Latin manuscripts of Gerard of Cremona (Laurentian 45 and British Museum, Sloane 2795) show so many discordances that they are passed over, except in a few instances. Baily has omitted the qualifying words $\mu \in i \zeta \omega \nu$ and $\dot{\varepsilon} \lambda \dot{a} \sigma \sigma \omega \nu$, consequently the variants in his edition refer only to magnitudes not so qualified in the catalogue.

NOTES ON THE STAR MAGNITUDES.

| Baily's No. | Star. | Notes. |
| :---: | :---: | :---: |
| 7 | URSA MINOR. <br> 7. $\quad 13 \gamma$ | All manuscripts give mag. 2. Peters adopts mag. 3, found only in Sûfi. |
|  | URSA MAJOR. |  |
| 15 | $\text { 7. } \quad 14 \tau$ | All manuscripts have mag. 4. No authority for Peters' mag. 4-5. |
| 18 | 10. $30 \varphi$ | Vat. 1594, Vat. 1038, Ven. 310 , Ven. 313, and Laur. 48 have mag. 4. The adopted mag. $4^{-5}$ is from Paris 2389, Ven. 302, Ven. 312, Vat. Reg. 90, Laur. 6, and all the Arabs. |
| 20 | 12. 9 ! | All manuscripts have mag. 3. No authority for Peters' mag. 3-4. |
| 21 | 13. $12 \kappa$ | All manuscripts have mag. 3. No authority for mag. 3-4. |
| 28 | 20. $33 \lambda$ | All manuscripts have mag. 3. No authority for mag. 3-4. |
| 29 | 21. $34 \mu$ | B. M. 7475, mag. 2; all others mag. 3. No authority for mag. 3-4. |
| 30 | 22. $52 \psi$ | B. M. 7475, mag. 3. |
| 3 I | 23. $54{ }^{2}$ | \}All manuscripts have mag. 3. No authority for mag. 3-4. |
| 32 35 | $\text { 24. } \quad 53 \xi$ |  |
| 35 | $\text { 27. } 85 \eta$ | B. M. 7475 , mag. 3 . |
|  | Draco. |  |
| 46 | 3. $23 \beta$ | All manuscripts have mag. 3. No authority for mag. 3-4. |
| 55 | 12. $63 \epsilon$ | All manuscripts have mag. 4. No authority for mag. 4-5. Sûfi has 4-3. Schjellerup gives Ptolemy's mag. 4-3, but the authority is unknown. |
| 57 58 | $\text { 14. } 61 \sigma$ |  |
| 58 59 | $\begin{array}{ll} 15 . & 52 v \\ 16 . & 60 \tau \end{array}$ | stars the authority for which is unknown. Sûfi gives mag. 5-4. |
| 62 | 19. $43 \varphi$ | All manuscripts have mag. 4. No authority for mag. 4-5. |
| 63 | 20. $27 f$ | B. M. 7475 , mag. 4. |
| 65 | 22. 18 g | B. M. 7475, mag. 6. |
| 69 | 26. 130 | B. M. 7475, mag. 3-2. |
| 70 | 27. 12 し | Most manuscripts have mag. 3. Magnitude 3-2 adopted by Peters is found in Laur. 45 (Gerard of Cremona). Magnitude in B. M. 7475 is doubtful; the scribe gives both $3^{-2}$ and $4^{-3}$. |
| 71 | 28. $10 i$ | Bod. 369 and B. M. Reg. 16, mag. 3. |
| 72 | $\text { 29. } 11 \text { a }$ |  |
| 73 74 | $\begin{array}{ll} \text { 30. } & 5 \kappa \\ \text { 3I. } & 1 \lambda \end{array}$ | Peters adopted mag. 3-4, which is found only in Sûf. |
|  | CEPHEUS. |  |
| 80 | 6. 20 | B. M. 7475 , mag. 3 . |
| 87 | Inf. 2. $27 \delta$ | All manuscripts have mag. 4. No authority for mag. 4-5. |
|  | BOOTES. |  |
| $\begin{array}{r}95 \\ \hline 108\end{array}$ | 8. $5 \mathbf{I} \mu$ | B. M. 7475 , mag. 6. |
| 108 | 2I. $4 \tau$ | B. M. 7475 , mag. 3 . |
|  | COR. BOR. |  |
| 111 112 | I. $\quad 5 a$ | B. M. 7475 has the singular error of mag. 5-4 for both stars. |
| 112 114 | $\begin{array}{ll}\text { 2. } & 3 \beta \\ \text { 4. } & 9 \pi\end{array}$ | Ven. 313 and Laur. 48, mag. 5 . |

Notes on the Star Magnitudes-continued.

| $\begin{array}{\|l\|} \hline \text { Baily's } \\ \text { No. } \end{array}$ | Star. | Notes. |
| :---: | :---: | :---: |
|  | hercules. |  |
| 122 | 4. 7 K | B. M. 7475, mag. 3; all other manuscripts mag. 4. No authority for mag. $4^{-5}$. |
| 123 | 5. $65 \delta$ | Vat. I594, Vat. 1038, Venice manuscripts 313, 3 12, and 310, and Laur. 48, mag. 4. |
| 124 | 6. $76 \lambda$ | B. M. 7475 , mag. 3. |
| 128 | 10. $92 \xi$ | All the Greek manuscripts have mag. 4, and the Arabs, B. M. 7475, Bod. 369, B. M. Reg. 16, Laur. 45, and Sloane 2795 , mag. $4^{-3}$, which is adopted. |
| 129 | II. $40 \zeta$ | All the Greeks and Baily, mag. 4; B. M. 7475, mag. 4-3; Bod. 369 and B. M. Reg. 16, mag. 3. |
| 130 | 12. 58 ¢ | All Greek manuscripts and Baily have mag. 5; B. M. 7475, Bod. 369, B. M. Reg. 16, and Laur. 45, mag. 4-3, which is better than mag. $5^{-6}$ adopted by Peters, for which no authority is known. |
| 132 | 14. 610 | All the Greeks and Baily have mag. 3; the Arabs mag. 5, which is adopted by Peters and accords with the star. |
| 133 | 15. $67 \pi$ | All the Greeks have mag. 4, which is adopted; the Arabs mag. 3. |
| 140 | 22. $82 y$ | Bod. 369 and B. M. Reg. 16, mag. 6-5. |
| 142 | 24. $35 \sigma$ |  |
| 144 | 26. $\quad 119$ | B. M. 7475 makes these stars mag. 6. |
| 145 146 | $\begin{array}{ll}27 . & 0 \\ 28 . & 1\end{array}$ | B. M. 7475 makes these stars mag. 6. |
| 147 | 29. $\left\{\begin{array}{l}\nu^{1} \\ \nu^{2}\end{array}\right.$ | \}All manuscripts omit magnitude of this star. |
|  | lyra. |  |
| 150 | 2. $\left\{\begin{array}{l}4 \epsilon^{1} \\ 5 \epsilon^{2}\end{array}\right.$ | B. M. 7475 , mag. 4 . |

## TABLE IX. <br> Collations of Manuscripts.

The Table of Collations gives the variants in longitude and latitude from Baily's Ptolemy in the following 26 manuscripts of the Almagest:

Greek: Paris 2389, 2390, 2391, and 2394; Venice 302, 303, 3 10, 3 II, 312, and 313; Vatican 1594, 1038, and Reg. 90; Laurentian 1, 47, and 48; Bodleian 3374, and Vienna 14.

Latin: Laurentian 6 and 45; Vienna 24, and British Museum Sloane 2795.
Arabic: British Museum 7475 and Reg. 16; Bodleian 369, and Laurentian 156.
For the purpose of comparison, readings agreeing with Baily are given in doubtful cases, and in those which instance peculiar mistakes of the copyist.

All Baily's readings which differ from the Catalogue are given in the Notes to the Catalogue.

Collations of Manuscripts-Latitudes-continued.

[^0]:    *Ueber die Fehler des Ptolemäischen Sternverzeichnisses. Vierteljahrsschrift Ast. Gesell. 1877.
    $\dagger$ Cf. Pliny (A. D. 77) Nat. Hist., Lib. II, cap. 26. "Hipparchus . . . . discovered a new star that had appeared in his own age and, by observing its motions on the day on which it shone, he was led to doubt whether it does not often happen that those stars have motion which we suppose to be fixed. And the same individual attempted what might seem presumptuous even in a deity, viz.: to number the stars for posterity and to express their relations by appropriate names; having previously devised instruments by which he might mark the places and the magnitudes of each individual star. In this way it might be easily discovered, not only whether they were destroyed or produced, but whether they changed their relative positions, and likewise whether they were increased or diminished; the heavens being thus left an inheritance to anyone who might be found competent to complete his plan."

[^1]:    *Reproduced on page 6.

[^2]:    *Chronology of Star Catalogues. Mems. R. A. S., vol. XLIII.

[^3]:    *The first by Abu Jafar Almansur (ob. A. D. 775), the predecessor of Harun Al Rashid, and the second by Al Mamon (ob. A. D. 833), who was the son of that celebrated Khalif.

[^4]:    *Professor Nallino, in his important and exhaustive work on the "Opus Astronomicum" of Al Battani, has fully discossed the mistakes he found in translating the Arabic manuscripts of that author.
    $\dagger$ The difference between the numerical value of letters with Eastern and Western Arabs is as shown in the table at the right.
    $\ddagger$ Roger Bacon (A. D. 1214-1292) wrote: "Though we have numerous translations of all the sciences by Gerard of Cremona, Michael Scot, Alfred the Englishman, Hermann the German, and William the Fleming, there is such a falsity in their works that none can sufficiently wonder at it. Not one of these translators had any true knowledge of the languages or of the sciences."
    §Monthly Notices, Vol. XXVIII.

[^5]:    *Photographs of the whole Catalogue in this manuscript are deposited at the Carnegie Institution of Washington.

[^6]:    *Photographs of the whole Catalogue in this manuscript are deposited at the Carnegie Institution of Washington.

[^7]:    *The only available information about Halley's edition is the following paragraph from the preface to the above work: "Quod vero hisce omnibus subjungere placuerit Ptolemæi Catalogum Fixarum Stellarum, alicui forsan mirum videatur, cum sit argumenti plane dissimilis, minime tamen dubito quin hoc mihi ignoscat, qui norit quot ab illis syderibus maculas abstersit, quantamque eis lucem affundit Cl . Hallejus; eandem scilicet, qua, Ptolemæo illa contemplante, enituerunt: cum diu in libris, tam Mss. quam editis, ob voces perturbatas numerosque confusos, illa cœli lumina crassis obvoluta fuissent tenebris."

[^8]:    *These three stars of the informata of Leo, and described by Ptolemy as in the figure $\pi \lambda$ 人óкamos, are three of the 12 stars which he designates as a $\mu$ aupós, the others being Nos. 40 to 43 , among the informatce of Ursa major, 219 , the last of the informate of Perseus, and 31 I to 3 I4, the four stars in Equuleus. It is difficult to conjecture why these stars should have been designated a a avobs (obscure). The magnitudes range from 4.I to 5.1 , the mean magnitude being 4.7. The constellations Equuleus and $\pi \lambda \delta \kappa \alpha \mu$ os are not mentioned by Aratus, Eratosthenes, Manilius, or Hipparchus in his commentary on Aratus.
    
     nices. (Petavius, Uranologion, p. 12.)

[^9]:    *Al Battāni. Pars II. $\quad \dagger$ Rubra canicula. $\ddagger$ Al Sûfi. Description des Etoiles Fixes. §Monthly Notices, Vol. XLV; and Eleventh Oriental Congress, 1897.

[^10]:    *Notices et Extraits. Tome VII.
    $\dagger$ M. D'Abbadie informed the writer that Fresnel told him that he learned in the Red Sea many current expressions not found in any native dictionaries.
